

On the theory of resonances in non-relativistic QED and related models

W. K. Abou Salem^a, J. Faupin^b, J. Fröhlich^c and I. M. Sigal^a

Abstract

We study the mathematical theory of quantum resonances for the standard model of non-relativistic QED and Nelson's model. In particular, we estimate the survival probability of metastable states in such models. We also provide a general definition of quantum resonances for systems coupled to massless fields and relate the resonances to poles of an analytic continuation of matrix elements of a resolvent.

1 Introduction

In this paper, we study the mathematical theory of resonances in the standard model of non-relativistic QED and in Nelson's model of electrons interacting with phonons. We define the (quantum) resonances as complex eigenvalues of a complex deformation of the quantum Hamiltonian of these models; (for a precise definition in our context see Section 2).

Resonances manifest themselves, physically, as long-lived metastable states and as “bumps” in the scattering cross-section as a function of energy. The life-times of the metastable states are given by the inverse of the “bumps widths”. It is believed - and is proved in some cases - that resonances correspond to poles of a meromorphic continuation of matrix elements of the resolvent of the physical Hamiltonian - on a certain dense set of vectors - across the essential spectrum to the “second Riemann sheet”. Since, in Quantum Mechanics, resonance poles are isolated, the metastability property can be established (if there is a small parameter in the problem) by using Fourier transform, contour deformation and Cauchy's theorem (see [1, 11]). The “bumpiness” of the cross-section can be shown as well.

In non-relativistic QED and phonon models, the resonance poles are *not isolated*; more precisely, a piece of essential spectrum is attached to every resonance eigenvalue of the spectrally deformed Hamiltonian. This is due to the fact that photons and phonons are massless. As a result, establishing the property of metastability and establishing the meaning of the resonance poles becomes a challenge. In this paper, we prove the metastability property of resonances and characterize them in terms of poles of a meromorphic continuation of the matrix elements of the resolvent on a dense set of vectors, for non-relativistic QED and Nelson's model.

The Hamiltonian of the QED model is defined as

$$H_g^{SM} := \sum_{j=1}^N \frac{1}{2m_j} (p_j + gA(x_j))^2 + V(x) + H_f, \quad (1.1)$$

where $x = (x_1, \dots, x_N)$, $p_j = i\nabla_j$ denotes the momentum of the j^{th} particle, V is the potential of the particle system, H_f is the photon (quantized electromagnetic field) Hamiltonian defined

below, and $A(x)$ denotes the quantized vector potential

$$A(x) = \int \frac{d^3k \chi(k)}{(2\pi)^3 \sqrt{2|k|}} (e^{ikx} \epsilon(k) a(k) + e^{-ikx} \overline{\epsilon(k)} a^*(k)). \quad (1.2)$$

Here a, a^* are annihilation and creation operators acting on the symmetric photon Fock space \mathcal{F}_s over $L^2(\mathbb{R}^3 \times \mathbb{Z}_2)$, χ is an ultraviolet cut-off that vanishes sufficiently fast at infinity, and $\epsilon(k)$ are two transverse polarization vectors. The QED Hamiltonian H_g^{SM} acts on the Hilbert space $\mathcal{H}_p \otimes \mathcal{F}_s$, where \mathcal{H}_p is the Hilbert space for N electrons. In (1.1), Zeeman terms coupling the magnetic moments of the electrons to the magnetic field are neglected.

To keep the analysis as simple as possible, we work out our results first for Nelson's model of non-relativistic particles without spin interacting with a scalar bosonic field. The interaction is then linear in the creation and annihilation operators. In section 5, we modify our analysis to cover the QED case.

The Hamiltonian of Nelson's model acts on $\mathcal{H}_p \otimes \mathcal{F}_s$, where $\mathcal{H}_p = L^2(\mathbb{R}^{3N})$, and \mathcal{F}_s is the symmetric Fock space over $L^2(\mathbb{R}^3)$, and is given by

$$H_g^N := H_p \otimes I + I \otimes H_f + W_g. \quad (1.3)$$

Here, $H_p = \sum_{j=1}^N p_j^2/2m_j + V$ denotes an N -particle Schrödinger operator on \mathcal{H}_p . We assume that its spectrum, $\sigma(H_p)$, consists of a sequence of discrete eigenvalues $\lambda_0, \lambda_1, \dots$ below some number Σ called the *ionization threshold*. Our analysis is based on the following assumptions, (A) through (C):

- (A) We assume that the potential $V(x)$ is dilatation analytic, i.e. the vector-function $\theta \mapsto V(e^\theta x)(-\Delta + 1)^{-1}$ has an analytic continuation to a small complex disc $D(0, \theta_0)$, for some small $\theta_0 > 0$.

An example of a dilatation-analytic potential V is the Coulomb potential for N electrons and one single fixed nucleus located at the origin. In this example $\theta \mapsto H_{p,\theta}$ is analytic of type (A) on $D(0, \theta_0)$, for θ_0 sufficiently small. For a molecule in the Born-Oppenheimer approximation the potential $V(x)$ is not dilatation-analytic. In this case, one has to use a more general notion of distortion analyticity (see [11]), which can be easily accommodated in our analysis.

For k in \mathbb{R}^3 , we denote by $a^*(k)$ and $a(k)$ the usual creation and annihilation operators on \mathcal{F}_s . They obey the canonical commutation relations

$$[a^*(k), a^*(k')] = [a(k), a(k')] = 0 \quad , \quad [a^*(k), a(k')] = \delta(k - k'). \quad (1.4)$$

The operator associated with the energy of the free boson field, H_f , is defined by

$$H_f = \int_{\mathbb{R}^3} \omega(k) a^*(k) a(k) dk, \quad (1.5)$$

where $\omega(k) = |k|$. The interaction W_g in (1.3) is supposed to be of the form

$$W_g = g\phi(G_x) \quad (1.6)$$

where

$$\phi(G_x) = \sum_{j=1}^N \int_{\mathbb{R}^3} \frac{\chi(k)}{|k|^{1/2-\mu}} [e^{-ik \cdot x_j} a^*(k) + e^{ik \cdot x_j} a(k)] dk. \quad (1.7)$$

As above, the function $\chi(k)$ denotes an ultraviolet cut-off, and the parameter μ is assumed to be positive.

- (B) We assume that χ is dilatation analytic, i.e. $\theta \mapsto \chi(e^{-\theta}k)$ has an analytic continuation from \mathbb{R} to a disc $D(0, \theta_0)$.

For instance, we can choose a function of the form $\chi(k) = e^{-k^2/\Lambda^2}$, for some fixed, arbitrarily large $\Lambda > 0$.

As stated at the beginning of the introduction, we would like to investigate the metastability of states “close to” unperturbed eigenstates. More precisely, we consider an unperturbed eigenvalue λ_j of $H_0 := H_p \otimes I + I \otimes H_f$, with $\lambda_0 < \lambda_j < \Sigma$, where $\lambda_0 = \inf(\sigma(H_0))$. To simplify our presentation, we assume that λ_j is non-degenerate, and we denote by $\Psi_j = \psi_j \otimes \Omega$ a normalized unperturbed eigenstate associated with λ_j . By the renormalization group analysis in [3, 4], we know that λ_j turns into a resonance $\lambda_{j,g}$, with $\text{Im}\lambda_{j,g} < 0$, as the interaction between the non-relativistic particles and the field is turned on.¹

- (C) In this paper, we assume that *Fermi’s Golden Rule* holds, which implies that $\text{Im}\lambda_{j,g} \leq -c_0g^2$, for some positive constant c_0 ; see for example [3, 4].

The main result of this paper is the following theorem.

Theorem 1.1 *Given H_g , Ψ_j , and $\lambda_{j,g}$ as above, and under the assumptions (A)-(C) formulated above, there exists some $g_0 > 0$ such that, for all $0 < g \leq g_0$ and times $t \geq 0$,*

$$(\Psi_j, e^{-itH_g}\Psi_j) = e^{-it\lambda_{j,g}} + O(g^{\min(\frac{2+4\mu}{5+2\mu}, \frac{1+2\mu}{4+2\mu})}), \quad (1.8)$$

where $\mu > 0$ appears in (1.7).

Remark 1.2 *We expect that our approach extends to situations where Fermi’s Golden Rule condition fails, as long as $\text{Im}\lambda_{j,g} < 0$, and that we can improve the exponent of g in the error term by using an initial state that is a better approximation of the “resonance state”; see section 3.*

Remark 1.3 *The analysis below, together with Theorem 3.3 in [15], gives an adiabatic theorem for quantum resonances in non-relativistic QED.*

The main difficulty in the proof comes from the fact that the unperturbed eigenvalue λ_j is the threshold of a branch of continuous spectrum. To overcome this difficulty, we introduce an infrared cut-off that opens a gap in the spectrum, and we control the error introduced by opening the gap using resolvent estimates.

Remark 1.4 *As we were completing this paper, there appeared an e-print [7] where lower and upper bounds for the lifetime of the metastable states considered here are estimated by somewhat different techniques.*

2 Dilatation analyticity and IR cut-off Hamiltonians

For $\theta \in \mathbb{R}$, we denote by \mathcal{U}_θ the unitary operator associated with the dilatations

$$x_j \mapsto e^\theta x_j, \quad j = 1, \dots, N, \quad k \mapsto e^{-\theta} k. \quad (2.1)$$

For H_g defined in (1.3) and $\theta \in \mathbb{R}$, we define

$$H_{g,\theta} := \mathcal{U}_\theta H_g \mathcal{U}_\theta^{-1}, \quad (2.2)$$

¹By resonances we here understand dilatation resonances; see Sect. 2.

By the above assumptions on V and χ , the family $H_{g,\theta}$ can be analytically extended to all θ belonging to a disc $D(0, \theta_0)$ in the complex plane. The relation

$$H_{g,\theta}^* = H_{g,\bar{\theta}}$$

holds for real θ and extends by analyticity to $\theta \in D(0, \theta_0)$. A direct computation gives

$$H_{g,\theta} = H_{p,\theta} \otimes I + e^{-\theta} I \otimes H_f + W_{g,\theta},$$

where $H_{p,\theta} = \mathcal{U}_\theta H_p \mathcal{U}_\theta^{-1}$ and $W_{g,\theta} := \mathcal{U}_\theta W_g \mathcal{U}_\theta^{-1}$. Note that $W_{g,\theta} = g\phi(G_{x,\theta})$, with

$$G_{x,\theta}(k) = e^{-(1+\mu)\theta} \frac{\chi(e^{-\theta}k)}{|k|^{1/2-\mu}} e^{-ik \cdot x}. \quad (2.3)$$

We now introduce an infra-red cut-off Hamiltonian

$$H_{g,\theta}^\sigma := H_{p,\theta} \otimes I + e^{-\theta} I \otimes H_f + W_{g,\theta}^{\geq \sigma}, \quad (2.4)$$

where $W_{g,\theta}^{\geq \sigma} := g\phi(\kappa_\sigma G_{x,\theta})$. Here κ_σ is an infrared cut-off function that we can choose, for instance, as $\kappa_\sigma = \mathbf{1}_{|k| \geq \sigma}$. We also define

$$W_{g,\theta}^{\leq \sigma} := W_{g,\theta} - W_{g,\theta}^{\geq \sigma} = g\phi((1 - \kappa_\sigma)G_{x,\theta}). \quad (2.5)$$

We then have that

$$H_{g,\theta} = H_{g,\theta}^\sigma + W_{g,\theta}^{\leq \sigma}. \quad (2.6)$$

Let us denote by $\mathcal{F}_s^{\geq \sigma}$ and $\mathcal{F}_s^{\leq \sigma}$ the symmetric Fock spaces over $L^2(\{k \in \mathbb{R}^3 : |k| \geq \sigma\})$ and $L^2(\{k \in \mathbb{R}^3 : |k| \leq \sigma\})$, respectively. It is well-known that there exists a unitary operator \mathcal{V} that maps $L^2(\mathbb{R}^{3N}; \mathcal{F}_s)$ to $L^2(\mathbb{R}^{3N}; \mathcal{F}_s^{\geq \sigma}) \otimes \mathcal{F}_s^{\leq \sigma}$, so that

$$\mathcal{V} H_{g,\theta}^\sigma \mathcal{V}^{-1} = H_{g,\theta}^{\geq \sigma} \otimes I + e^{-\theta} I \otimes H_f^{\leq \sigma}. \quad (2.7)$$

Here, $H_{g,\theta}^{\geq \sigma}$ acts on $L^2(\mathbb{R}^{3N}; \mathcal{F}_s^{\geq \sigma})$ and is defined by

$$H_{g,\theta}^{\geq \sigma} := H_{p,\theta} + e^{-\theta} H_f^{\geq \sigma} + W_{g,\theta}^{\geq \sigma}. \quad (2.8)$$

The operators $H_f^{\geq \sigma}$ and $H_f^{\leq \sigma}$ denote the restrictions of H_f to $\mathcal{F}_s^{\geq \sigma}$ and $\mathcal{F}_s^{\leq \sigma}$ respectively. We note the following estimate that will often be used in this paper:

$$\left\| W_{g,\theta}^{\leq \sigma} [H_f + 1]^{-1} \right\| \leq Cg\sigma^{1/2+\mu}, \quad (2.9)$$

where $\mu > 0$, C is a positive constant, and $\theta \in D(0, \theta_0)$.

We now consider an unperturbed isolated eigenvalue λ_j of H_0 . To simplify our analysis, we assume that λ_j is non-degenerate. Let

$$d_j := \text{dist}(\lambda_j; \sigma(H_p) \setminus \{\lambda_j\}). \quad (2.10)$$

It is shown in [3, 4, 6] that, as the perturbation W_g is turned on, the eigenvalue λ_j turns into a resonance $\lambda_{j,g}$ of H_g . In other words, for $\theta \in D(0, \theta_0)$ with $\text{Im}(\theta) > 0$, there exists a non-degenerate eigenvalue $\lambda_{j,g}$ of $H_{g,\theta}$ not depending on θ , with $\text{Re}\lambda_{j,g} = \lambda_j + O(g^2)$, $\text{Im}\lambda_{j,g} = O(g^2)$, and, if Fermi's Golden Rule condition holds, $\text{Im}\lambda_{j,g} \leq -c_0 g^2$, for some positive constant c_0 .

Similarly, the operator $H_{g,\theta}^{\geq\sigma}$ has an eigenvalue $\lambda_{j,g}^{\geq\sigma}$ bifurcating from the eigenvalue λ_j of H_0 having the same properties as $\lambda_{j,g}$, with the important exception that $\lambda_{j,g}^{\geq\sigma}$ depends on θ . The reason for this is that $H_{g,\theta+r}^{\geq\sigma} \neq \mathcal{U}(r)H_{g,\theta}^{\geq\sigma}\mathcal{U}(-r)$, $r \in \mathbb{R}$. Furthermore, we have the crucial property (see Proposition 4.1) that the eigenvalue $\lambda_{j,g}^{\geq\sigma}$ of $H_{g,\theta}^{\geq\sigma}$ is isolated from the rest of the spectrum of $H_{g,\theta}^{\geq\sigma}$. More precisely,

$$\text{dist}\left(\lambda_{j,g}^{\geq\sigma}, \sigma(H_{g,\theta}^{\geq\sigma}) \setminus \{\lambda_{j,g}^{\geq\sigma}\}\right) \geq C\sigma, \quad (2.11)$$

for some positive constant C independent of σ .

It is tempting to treat $H_{g,\theta}$ as a perturbation of $H_{g,\theta}^{\geq\sigma}$. However, we have to take care of the difference between $\lambda_{j,g}$ and $\lambda_{j,g}^{\geq\sigma}$. In order to deal with this problem, we “renormalize” the unperturbed part $H_{g,\theta}^{\geq\sigma}$ by setting

$$\tilde{H}_{g,\theta}^{\sigma} = H_{g,\theta}^{\geq\sigma} + \left(\lambda_{j,g} - \lambda_{j,g}^{\geq\sigma}\right) \mathcal{V}^{-1}(P_{g,\theta}^{\geq\sigma} \otimes I) \mathcal{V}. \quad (2.12)$$

Here $P_{g,\theta}^{\geq\sigma}$ denotes the spectral projection onto the eigenspace associated with the eigenvalue $\lambda_{j,g}^{\geq\sigma}$ of $H_{g,\theta}^{\geq\sigma}$. As in (2.7), we have the representation

$$\mathcal{V} \tilde{H}_{g,\theta}^{\sigma} \mathcal{V}^{-1} = \tilde{H}_{g,\theta}^{\geq\sigma} \otimes I + e^{-\theta} I \otimes H_f^{\leq\sigma}, \quad (2.13)$$

where we have set

$$\tilde{H}_{g,\theta}^{\geq\sigma} = H_{g,\theta}^{\geq\sigma} + \left(\lambda_{j,g} - \lambda_{j,g}^{\geq\sigma}\right) P_{g,\theta}^{\geq\sigma}. \quad (2.14)$$

By (2.14), we see that $\lambda_{j,g}$ is a non-degenerate eigenvalue of $\tilde{H}_{g,\theta}^{\geq\sigma}$. In Proposition 4.3 we will show that, for $g^2 \ll \sigma < g^{\frac{3}{2+\mu}}$, there exists a positive constant C such that

$$\left|\lambda_{j,g} - \lambda_{j,g}^{\geq\sigma}\right| \leq Cg^{4-\frac{3}{2+\mu}}, \quad (2.15)$$

and that the operator $\tilde{H}_{g,\theta}^{\geq\sigma}$ still has a gap of order $O(\sigma)$ around $\lambda_{j,g}$. Then the decomposition (2.4) is replaced by

$$H_{g,\theta} = \tilde{H}_{g,\theta}^{\sigma} + \tilde{W}_{g,\theta}^{\leq\sigma}, \quad (2.16)$$

where

$$\tilde{W}_{g,\theta}^{\leq\sigma} = W_{g,\theta}^{\leq\sigma} - \left(\lambda_{j,g} - \lambda_{j,g}^{\geq\sigma}\right) \mathcal{V}^{-1} P_{g,\theta}^{\geq\sigma} \otimes I \mathcal{V}. \quad (2.17)$$

Let $H_{\star}^{\#}$ denote one of the operators H_g , $H_{g,\theta}$, $H_{g,\theta}^{\sigma}$ or $H_{g,\theta}^{\geq\sigma}$. We write its resolvent by using the notation $R_{\star}^{\#}(z) = \left[H_{\star}^{\#} - z\right]^{-1}$. Similarly, we define $\tilde{R}_{\star}^{\#}(z) = \left[\tilde{H}_{\star}^{\#} - z\right]^{-1}$.

3 Proof of Theorem 1.1

We begin with some notation. We consider an interval I of size δ , containing λ_j , such that $\delta < \frac{1}{2}d_j$. For concreteness, let

$$I = \left(\lambda_j - \frac{\delta}{2}, \lambda_j + \frac{\delta}{2}\right). \quad (3.1)$$

Define, in addition,

$$I_1 = \left(\lambda_j - \frac{\delta}{4}, \lambda_j + \frac{\delta}{4} \right). \quad (3.2)$$

We consider a smooth function $f \in C_0^\infty(I)$, $\text{Ran}(f) \in [0, 1]$, such that $f = 1$ on I_1 . It is known that there exists an almost analytic extension \tilde{f} of f such that

$$\tilde{f} = 1 \text{ on } \{z \in \mathbb{C} \mid \text{Re}(z) \in I_1\} \quad , \quad \text{supp}(\tilde{f}) \subset \{z \in \mathbb{C} \mid \text{Re}(z) \in I\}, \quad (3.3)$$

and $\left| (\partial_z \tilde{f})(z) \right| = O(\delta^{-1} |\text{Im}(z)/\delta|^n)$, for any $n \in \mathbb{N}$. We shall use these properties of \tilde{f} in the sequel.

We begin with the following proposition.

Proposition 3.1 *Given H_g , Ψ_j , $\lambda_{j,g}$ and f as above, there exists $g_0 > 0$ such that, for all $0 < g \leq g_0$, $\delta = C\sigma$, $C > 1$, and $\sigma = g^{2-\min(\frac{2+4\mu}{5+2\mu}, \frac{1+2\mu}{4+2\mu})}$,*

$$(\Psi_j, e^{-itH_g} f(H_g) \Psi_j) = e^{-it\lambda_{j,g}} + O(g^{\min(\frac{2+4\mu}{5+2\mu}, \frac{1+2\mu}{4+2\mu})}), \quad (3.4)$$

for all times $t \geq 0$.

We subdivide the proof of Proposition 3.1 into several steps, deferring the proof of some technical ingredients to the following section. We extend a method due to Hunziker to prove Proposition 3.1, see [1] or [11]. Let $\mathcal{N}(\theta)$ be a punctured neighbourhood of λ_j such that $\mathcal{N}(\theta) \cap \sigma(\tilde{H}_{g,\theta}^{\geq \sigma}) = \lambda_{j,g}$ and $I \subset \mathcal{N}(\theta) \cup \{\lambda_j\}$. Let $\Gamma \subset \mathcal{N}(\theta)$ be a contour that encloses I and $\lambda_{j,g}$. For z inside Γ , we have that

$$\tilde{R}_{g,\theta}^{\geq \sigma}(z) = \frac{P_{g,\theta}^{\geq \sigma}}{\lambda_{j,g} - z} + \hat{R}_{g,\theta}^{\geq \sigma}(z), \quad (3.5)$$

where $P_{g,\theta}^{\geq \sigma}$ denotes the spectral projection onto the eigenspace associated to the eigenvalue $\lambda_{j,g}$ of $\tilde{H}_{g,\theta}^{\geq \sigma}$, that is

$$P_{g,\theta}^{\geq \sigma} = \frac{1}{2\pi i} \oint_{\mathcal{C}} \tilde{R}_{g,\theta}^{\geq \sigma}(z) dz, \quad (3.6)$$

where \mathcal{C} denotes a circle centered at $\lambda_{j,g}$ with radius chosen so that $\mathcal{C} \subset \rho(H_{g,\theta}^{\geq \sigma}) \cap \mathcal{N}(\theta)$, and the regular part, $\hat{R}_{g,\theta}^{\geq \sigma}(z)$, is given by

$$\hat{R}_{g,\theta}^{\geq \sigma}(z) = \frac{1}{2\pi i} \oint_{\Gamma} \tilde{R}_{g,\theta}^{\geq \sigma}(w) (w - z)^{-1} dw, \quad (3.7)$$

where z is inside Γ . Note that

$$\hat{R}_{g,\theta}^{\geq \sigma} P_{g,\theta}^{\geq \sigma} = P_{g,\theta}^{\geq \sigma} \hat{R}_{g,\theta}^{\geq \sigma} = 0, \quad (3.8)$$

and

$$(P_{g,\theta}^{\geq \sigma})^2 = P_{g,\theta}^{\geq \sigma}. \quad (3.9)$$

We will need the following easy lemma, which follows from dilatation analyticity and Stone's theorem.

Lemma 3.2 *Assume that the infrared cut-off parameter σ is chosen such that $g^2 \ll \sigma < g^{\frac{3}{2+\mu}} \ll 1$. Then*

$$(\Psi_j, e^{-itH_g} f(H_g) \Psi_j) = A(t, \bar{\theta}) - A(t, \theta) + B(t, \bar{\theta}) - B(t, \theta), \quad (3.10)$$

for $\theta \in D(0, \theta_0)$, $\text{Im}\theta > 0$, where

$$A(t, \theta) = \frac{1}{2\pi i} \int_{\mathbb{R}} e^{-itz} f(z) \left(\Psi_{j, \bar{\theta}}, \tilde{R}_{g, \theta}^{\sigma}(z) \Psi_{j, \theta} \right) dz, \quad (3.11)$$

$$B(t, \theta) = \frac{1}{2\pi i} \int_{\mathbb{R}} e^{-itz} f(z) \left(\Psi_{j, \bar{\theta}}, \tilde{R}_{g, \theta}^{\sigma}(z) \sum_{n \geq 1} \left(-\tilde{W}_{g, \theta}^{\leq \sigma} \tilde{R}_{g, \theta}^{\sigma}(z) \right)^n \Psi_{j, \theta} \right) dz. \quad (3.12)$$

Proof. By Stone's theorem,

$$\left(\Psi_j, e^{-itH_g} f(H_g) \Psi_j \right) = \lim_{\varepsilon \searrow 0} \frac{1}{2\pi i} \int_{\mathbb{R}} e^{-itz} f(z) \left(\Psi_j, [R_g(z - i\varepsilon) - R_g(z + i\varepsilon)] \Psi_j \right) dz. \quad (3.13)$$

Since H_g and Ψ_j are dilatation analytic, this implies

$$\left(\Psi_j, e^{-itH_g} f(H_g) \Psi_j \right) = F(t, \bar{\theta}) - F(t, \theta), \quad (3.14)$$

where

$$F(t, \theta) = \frac{1}{2\pi i} \int_{\mathbb{R}} e^{-itz} f(z) \left(\Psi_{j, \bar{\theta}}, R_{g, \theta}(z) \Psi_{j, \theta} \right) dz, \quad (3.15)$$

for $\theta \in D(0, \theta_0)$. It follows from Lemma 4.4, below, that we can expand $R_{g, \theta}(z)$ into a Neumann series, which is convergent under our assumptions on g and σ if Fermi's Golden Rule holds. We obtain

$$F(t, \theta) = A(t, \theta) + B(t, \theta), \quad (3.16)$$

for $\theta \in D(0, \theta_0)$, $\text{Im}\theta > 0$, and hence the claim of the lemma is proven. \square

In what follows, we fix $\theta \in D(0, \theta_0)$ with $\text{Im}\theta > 0$. We estimate $A(t, \bar{\theta}) - A(t, \theta)$ and $B(t, \bar{\theta}) - B(t, \theta)$ in the following two lemmata.

Lemma 3.3 For $g^2 \ll \sigma < \delta < g^{\frac{3}{2+\mu}} \ll 1$, we have

$$A(t, \bar{\theta}) - A(t, \theta) = e^{-it\lambda_{j, g}} + O(\delta g^2 / \sigma^{-2}) + O(g^2 \sigma^{-1}),$$

for all $t \geq 0$.

Proof. It follows from the spectral theorem that

$$\mathcal{V} \tilde{R}_{g, \theta}^{\sigma}(z) \mathcal{V}^{-1} = \int_{\sigma(H_f^{\leq \sigma})} \tilde{R}_{g, \theta}^{\geq \sigma}(z - e^{-\theta} x) \otimes dE_{H_f^{\leq \sigma}}(x), \quad (3.17)$$

where $E_{H_f^{\leq \sigma}}$ are the spectral projections of $H_f^{\leq \sigma}$; see for example [12]. Furthermore, $\mathcal{V} \Psi_{j, \theta} = \psi_{j, \theta} \otimes \Omega^{\geq \sigma} \otimes \Omega^{\leq \sigma}$, where $\Omega^{\geq \sigma}$ (respectively $\Omega^{\leq \sigma}$) denotes the vacuum in $\mathcal{F}_s^{\geq \sigma}$ (in $\mathcal{F}_s^{\leq \sigma}$). Inserting this into (3.11) and using (3.17), we get

$$A(t, \theta) = \frac{1}{2i\pi} \int_{\mathbb{R}} e^{-itz} f(z) \left(\psi_{j, \bar{\theta}} \otimes \Omega^{\geq \sigma}, \tilde{R}_{g, \theta}^{\geq \sigma}(z) \psi_{j, \theta} \otimes \Omega^{\geq \sigma} \right) dz. \quad (3.18)$$

From Proposition 4.1, we know that the spectrum of $H_{g, \theta}^{\geq \sigma}$ is of the form pictured in figure 1. In particular, a gap of order σ opens between the non-degenerate eigenvalue $\lambda_{j, g}^{\geq \sigma}$ and the essential spectrum of $H_{g, \theta}^{\geq \sigma}$. By Proposition 4.3, the same holds for $\tilde{H}_{g, \theta}^{\geq \sigma}$ instead of $H_{g, \theta}^{\geq \sigma}$, with $\lambda_{j, g}$ replacing $\lambda_{j, g}^{\geq \sigma}$, since $|\lambda_{j, g} - \lambda_{j, g}^{\geq \sigma}| \leq Cg^{4 - \frac{3}{2+\mu}}$, and we assumed that $g^2 \ll \sigma < g^{\frac{3}{2+\mu}}$.

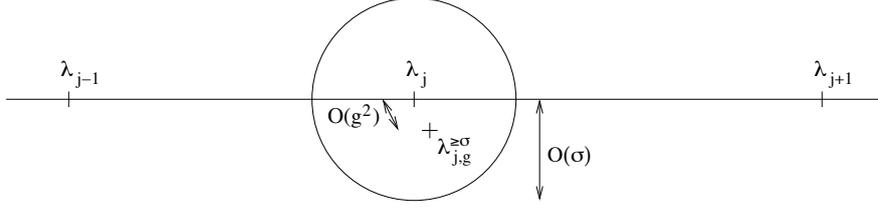

Figure 1: **Spectrum of $H_{g,\theta}^{\geq \sigma}$ around λ_j**

Let us begin to estimate $A(t, \bar{\theta}) - A(t, \theta)$ by considering the contribution of the regular part, $\widehat{R}_{g,\theta}^{\geq \sigma}(z)$, in $A(t, \theta)$. By applying Green's theorem, we find that

$$\begin{aligned}
R(t, \theta) &:= \frac{1}{2i\pi} \int_{\mathbb{R}} e^{-itz} f(z) \left(\Psi_{j,\bar{\theta}}, \widehat{R}_{g,\theta}^{\geq \sigma}(z) \Psi_{j,\theta} \right) dz \\
&= \frac{1}{2i\pi} \int_{\Gamma(\gamma_1)} e^{-itz} \tilde{f}(z) \left(\Psi_{j,\bar{\theta}}^{\geq \sigma}, \widehat{R}_{g,\theta}^{\geq \sigma}(z) \Psi_{j,\theta}^{\geq \sigma} \right) dz \\
&\quad + \frac{1}{2i\pi} \iint_{D(\gamma_1)} e^{-itz} (\partial_{\bar{z}} \tilde{f})(z) \left(\Psi_{j,\bar{\theta}}^{\geq \sigma}, \widehat{R}_{g,\theta}^{\geq \sigma}(z) \Psi_{j,\theta}^{\geq \sigma} \right) dz d\bar{z},
\end{aligned} \tag{3.19}$$

where $\Psi_{j,\theta}^{\geq \sigma} = \psi_{j,\theta} \otimes \Omega^{\geq \sigma}$, and $\Gamma(\gamma_1)$ and $D(\gamma_1)$ denote respectively the curve and the domain pictured in figure 2, such that the interval I_0 strictly contains I .

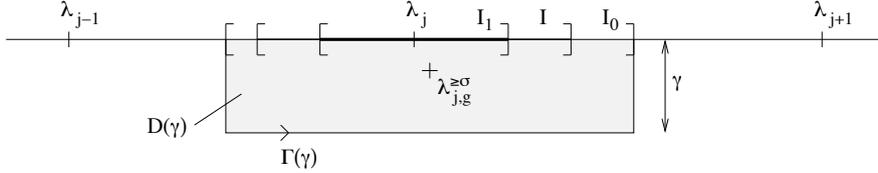

Figure 2: **Deformation of the path of integration**

By Proposition 4.1 and (3.7), the regular part $\widehat{R}_{g,\theta}^{\geq \sigma}(z)$ in (3.5) is analytic in $z \in D(\gamma_1)$ and satisfies

$$\left\| \widehat{R}_{g,\theta}^{\geq \sigma}(z) \right\| \leq \frac{C}{\text{dist}(z, \sigma(\widehat{H}_{g,\theta}^{\geq \sigma}) \setminus \{\lambda_{j,g}\})}, \tag{3.20}$$

where C is a positive constant. We also have from (3.8) that

$$P_{0,\theta}^{\geq \sigma} \widehat{R}_{g,\theta}^{\geq \sigma}(z) P_{0,\theta}^{\geq \sigma} = (P_{0,\theta}^{\geq \sigma} - P_{g,\theta}^{\geq \sigma}) \widehat{R}_{g,\theta}^{\geq \sigma}(z) (P_{0,\theta}^{\geq \sigma} - P_{g,\theta}^{\geq \sigma}), \tag{3.21}$$

and from (3.9) that

$$P_{0,\theta}^{\geq \sigma} = P_{0,\theta}^{\geq \sigma} P_{g,\theta}^{\geq \sigma} P_{0,\theta}^{\geq \sigma} - (P_{g,\theta}^{\geq \sigma} - P_{0,\theta}^{\geq \sigma}) (P_{g,\theta}^{\geq \sigma} - 1) (P_{g,\theta}^{\geq \sigma} - P_{0,\theta}^{\geq \sigma}), \tag{3.22}$$

and from Proposition (4.2), below, that

$$\|P_{g,\theta}^{\geq \sigma} - P_{0,\theta}^{\geq \sigma}\| \leq Cg\sigma^{-1/2}, \tag{3.23}$$

for some positive constant C . Thus, by (3.19) – (3.23), our assumptions on \tilde{f} and the fact that $|I_0| = O(\delta)$, we get

$$|R(t, \theta)| = O(\delta g^2 \sigma^{-2} e^{-t\gamma_1}) + O(|\gamma_1/\delta|^n), \tag{3.24}$$

where $0 < \gamma_1 < \sigma \sin(\text{Im}\theta)$, and any $n \in \mathbb{N}$. Similarly, for the contribution of the regular part $\widehat{R}_{g,\bar{\theta}}^{\geq \sigma}$ in $A(t, \bar{\theta})$, we have the following estimate

$$|R(t, \bar{\theta})| = O(\delta g^2 \sigma^{-2} e^{-t\gamma_2}) + O(|\gamma_2/\delta|^n), \quad (3.25)$$

where $0 < \gamma_2 < \sin(\text{Im}\theta)\sigma$, and any $n \in \mathbb{N}$.

Next, we estimate the singular part of $A(t, \bar{\theta}) - A(t, \theta)$. It is given by

$$S(t, \bar{\theta}) - S(t, \theta) := \frac{C_g^\sigma(\bar{\theta})}{2i\pi} \int_{\mathbb{R}} e^{-itz} f(z) (z - \overline{\lambda_{j,g}})^{-1} dz - \frac{C_g^\sigma(\theta)}{2i\pi} \int_{\mathbb{R}} e^{-itz} f(z) (z - \lambda_{j,g})^{-1} dz, \quad (3.26)$$

where we use the notation

$$C_g^\sigma(\theta) = \left(\Psi_j^{\geq \sigma}(\bar{\theta}), P_{g,\theta}^{\geq \sigma} \Psi_{j,\theta}^{\geq \sigma} \right). \quad (3.27)$$

By Proposition 4.2, we know that

$$C_g^\sigma(\theta) = 1 + O(g^2 \sigma^{-1}). \quad (3.28)$$

We deform the path of integration as we did above, adding a circle C_ρ of radius ρ around $\lambda_{j,g}$. This yields

$$\begin{aligned} S(t, \bar{\theta}) - S(t, \theta) &= \frac{1}{2i\pi} \int_{\Gamma(\gamma_3)} e^{-itz} \tilde{f}(z) \left[\frac{C_g^\sigma(\bar{\theta})}{z - \overline{\lambda_{j,g}}} - \frac{C_g^\sigma(\theta)}{z - \lambda_{j,g}} \right] dz \\ &\quad + \frac{1}{2i\pi} \int_{C_\rho} e^{-itz} \tilde{f}(z) \left[\frac{C_g^\sigma(\bar{\theta})}{z - \overline{\lambda_{j,g}}} - \frac{C_g^\sigma(\theta)}{z - \lambda_{j,g}} \right] dz \\ &\quad + \frac{1}{2i\pi} \iint_{D(\gamma_3) \setminus D_\rho} e^{-itz} (\partial_{\bar{z}} \tilde{f})(z) \left[\frac{C_g^\sigma(\bar{\theta})}{z - \overline{\lambda_{j,g}}} - \frac{C_g^\sigma(\theta)}{z - \lambda_{j,g}} \right] dz d\bar{z}, \end{aligned} \quad (3.29)$$

for all $\rho > 0$ sufficiently small, where D_ρ denotes the disc of radius ρ centered at $\lambda_{j,g}$, and $0 < \gamma_3 < \sin(\text{Im}\theta)\sigma$. The first integral can be estimated by using arguments similar to those used to estimate the regular part, (3.28), and the fact that

$$\text{Im}\lambda_{j,g} = O(g^2).$$

We then obtain that

$$\left| \frac{1}{2i\pi} \int_{\Gamma(\gamma_3)} e^{-itz} \tilde{f}(z) \left[\frac{C_g^\sigma(\bar{\theta})}{z - \overline{\lambda_{j,g}}} - \frac{C_g^\sigma(\theta)}{z - \lambda_{j,g}} \right] dz \right| = O(\delta g^2 \sigma^{-2} e^{-t\gamma_3}), \quad (3.30)$$

for $0 < g^2 < \sigma \ll 1$. Similarly, since $(\partial_{\bar{z}} \tilde{f}) = 0$ on $\{z \mid \text{Re}(z) \in I_1\}$, we see that the third integral in the rhs of (3.29) is independent of ρ , for ρ sufficiently small, and that

$$\left| \frac{1}{2i\pi} \iint_{D(\gamma_3) \setminus D_\rho} e^{-itz} (\partial_{\bar{z}} \tilde{f})(z) \left[\frac{C_g^\sigma(\bar{\theta})}{z - \overline{\lambda_{j,g}}} - \frac{C_g^\sigma(\theta)}{z - \lambda_{j,g}} \right] dz \right| = O(|\gamma_3/\delta|^n), \quad (3.31)$$

for any $n \in \mathbb{N}$. It remains to estimate the second integral on the right hand side of (3.29). Taking the limit as $\rho \rightarrow 0$ leads to the ‘‘residue’’ $C_g^\sigma(\theta) e^{-it\lambda_{j,g}} \tilde{f}(\lambda_{j,g})$. Since, by construction, $\tilde{f} = 1$ on $\{z \mid \text{Re}(z) \in I_1\}$, we get

$$\lim_{\rho \rightarrow 0} \frac{1}{2i\pi} \int_{C_\rho} e^{-itz} \tilde{f}(z) \left[\frac{C_g^\sigma(\bar{\theta})}{z - \overline{\lambda_{j,g}}} - \frac{C_g^\sigma(\theta)}{z - \lambda_{j,g}} \right] dz = C_g^\sigma(\theta) e^{-it\lambda_{j,g}}. \quad (3.32)$$

The claim of the lemma follows from (3.24) – (3.32). \square

Lemma 3.4 *Assume that the infrared cutoff parameter σ is chosen such that $g^2 \ll \sigma < g^{\frac{3}{2+\mu}} \ll 1$. Then, for all times $t \geq 0$, we have that*

$$|B(t, \bar{\theta}) - B(t, \theta)| = O(\delta g^{-2}(\sigma^{\frac{1}{2}+\mu} + g^{2-\frac{3}{2+\mu}})), \quad (3.33)$$

where $B(t, \theta)$ is defined in (3.12).

Proof. Recall that

$$B(t, \theta) = \sum_{n \geq 1} B^n(t, \theta), \quad (3.34)$$

where

$$B^n(t, \theta) = \frac{1}{2i\pi} \int_{\mathbb{R}} e^{-itz} f(z) \left(\Psi_j(\bar{\theta}), \tilde{R}_{g,\theta}^\sigma(z) \left(-\tilde{W}_{g,\theta}^{\leq \sigma} \tilde{R}_{g,\theta}^\sigma(z) \right)^n \Psi_j(\theta) \right) dz. \quad (3.35)$$

It follows from (3.35) and Lemma 4.4 that²

$$|B^n(t, \theta)| = O(\delta g^{-2}(\sigma^{\frac{1}{2}+\mu} + g^{2-\frac{3}{2+\mu}})^n), \quad (3.36)$$

uniformly in $t \geq 0$. Together with (3.34) and the assumption on σ and g , it follows that

$$|B(t, \theta)| = O(\delta g^{-2}(\sigma^{\frac{1}{2}+\mu} + g^{2-\frac{3}{2+\mu}})), \quad (3.37)$$

uniformly in t . One can similarly show that

$$|B(t, \bar{\theta})| = O(\delta g^{-2}(\sigma^{\frac{1}{2}+\mu} + g^{2-\frac{3}{2+\mu}})), \quad (3.38)$$

and hence the claim of the lemma follows. \square

Proof of Proposition 3.1 . It follows from Lemmata 3.2, 3.3 and 3.4 that

$$(\Psi_j, e^{-itH_g} f(H_g) \Psi_j) = e^{-it\lambda_{j,g}} + O(\delta g^2 \sigma^{-2}) + O(\delta g^{-2} \sigma^{1/2+\mu}) + O(\delta g^{-\frac{3}{2+\mu}}) + O(g^2 \sigma^{-1}), \quad t \geq 0. \quad (3.39)$$

Let $\delta = C\sigma$, for some $C > 1$. We optimize the estimate on the error term by choosing

$$\sigma = g^{2-\min(\frac{2+4\mu}{5+2\mu}, \frac{1+2\mu}{4+2\mu})}, \quad (3.40)$$

and hence the claim of the proposition is proven. \square

Proof of Theorem 1.1. Proposition 3.1 implies that, for $t = 0$,

$$(\Psi_j, (1 - f(H_g)) \Psi_j) = \|\sqrt{1 - f(H_g)} \Psi_j\|^2 = O(g^{\min(\frac{2+4\mu}{5+2\mu}, \frac{1+2\mu}{4+2\mu})}), \quad (3.41)$$

which, together with the boundedness of the unitary operator e^{-itH_g} and Proposition 3.1, for arbitrary $t > 0$, yields

$$\begin{aligned} (\Psi_j, e^{-itH_g} \Psi_j) &= (\Psi_j, e^{-itH_g} (1 - f(H_g) + f(H_g)) \Psi_j) \\ &= (\Psi_j, e^{-itH_g} f(H_g) \Psi_j) + O(\|\sqrt{1 - f(H_g)} \Psi_j\|^2) \\ &= e^{-it\lambda_{j,g}} + O(g^{\min(\frac{2+4\mu}{5+2\mu}, \frac{1+2\mu}{4+2\mu})}). \end{aligned}$$

\square

²We note that it follows from (2.17) that estimate (3.36) can be improved if one uses instead of Ψ_j a state that is a better approximation to the resonance eigenstate.

4 The Hamiltonian $H_{g,\theta}^\sigma$

In this section, we study the operator $H_{g,\theta}^\sigma$ used in the previous section as an approximation of $H_{g,\theta}$. We use the Feshbach map, [3, 4], defined for a projection P and a closed operator H whose domain is contained in $\text{Ran}(P)$, by

$$\mathcal{F}_P(H) = PHP - PH\bar{P} [\bar{P}H\bar{P}]^{-1} \bar{P}HP, \quad (4.1)$$

where $\bar{P} = 1 - P$. Note that the domain of \mathcal{F}_P consists of operators H such that

$$[\bar{P}H\bar{P}]^{-1}|_{\text{Ran}(\bar{P})}, \quad PH\bar{P} [\bar{P}H\bar{P}]^{-1}|_{\text{Ran}(\bar{P})}, \quad [\bar{P}H\bar{P}]^{-1} \bar{P}HP \quad (4.2)$$

extend to bounded operators. We begin with the following proposition.

Proposition 4.1 *Suppose $0 < g^2 \ll \sigma \ll 1$. Then, for $\theta \in D(0, \theta_0)$ such that $\text{Im}\theta \neq 0$, the spectrum of $H_{g,\theta}^{\geq \sigma}$ in the disc $D(\lambda_j, \sigma/2)$ consists of a single eigenvalue*

$$\sigma(H_{g,\theta}^{\geq \sigma}) \cap D(\lambda_j, \sigma/2) = \{\lambda_{j,g}^{\geq \sigma}\}. \quad (4.3)$$

Furthermore, there exists $\varepsilon > 0$ such that, for all z in $D(\lambda_j, \sigma/3)$ such that $|z - \lambda_{j,g}^{\geq \sigma}| \gg g^{2+\varepsilon}$,

$$\left\| R_{g,\theta}^{\geq \sigma}(z) \right\| \leq \frac{C}{\text{dist}(z, \sigma(H_{g,\theta}^{\geq \sigma}))}, \quad (4.4)$$

for some positive constant C .

Proof. Let $P_\theta := P_{p,\theta} \otimes P_\Omega$. For $z \in D(\lambda_j, \sigma/2)$, the operator $H_{g,\theta}^{\geq \sigma} - z$ is in the domain of \mathcal{F}_{P_θ} . Indeed, from $g\sigma^{-1/2} \ll 1$, we have that for any z in $D(\lambda_j, \sigma/2)$

$$\|(H_f + 1)^n (H_{g,\theta}^{\geq \sigma} - z)^{-1} \bar{P}_\theta\| \leq C\sigma^{-1}, \quad n = 0, 1, \quad (4.5)$$

for some positive constant C . Hence the operator $\bar{P}_\theta (H_{g,\theta}^{\geq \sigma} - z) \bar{P}_\theta$ is invertible on $\text{Ran} \bar{P}_\theta$. Moreover, $W_{g,\theta}^{\geq \sigma}$ is $(H_f + 1)$ -bounded.

Note that our choice of P_θ yields $P_\theta W_{g,\theta}^{\geq \sigma} P_\theta = 0$. Therefore

$$\mathcal{F}_{P_\theta}(H_{g,\theta}^{\geq \sigma} - z) = (\lambda_j - z) P_\theta - P_\theta W_{g,\theta}^{\geq \sigma} \bar{P}_\theta \left[\bar{P}_\theta H_{g,\theta}^{\geq \sigma} \bar{P}_\theta - z \right]^{-1} \bar{P}_\theta W_{g,\theta}^{\geq \sigma} P_\theta. \quad (4.6)$$

The non-degeneracy of λ_j implies that $\mathcal{F}_{P_\theta}(H_{g,\theta}^{\geq \sigma} - z)$ can be written as $[\lambda_j - z + a(z)]P_\theta$, where $a(z)$ is an analytic function from $D(\lambda_j, \sigma/2) \rightarrow \mathbb{C}$. Following [3, 5] (see also Proposition 4.3 below), we have

$$a(z) = g^2 Z_{j,\theta} + O(g^{2+\varepsilon}) \quad (4.7)$$

for some $\varepsilon > 0$, where $Z_{j,\theta} := Z_{j,\theta}^{\text{od}} + Z_{j,\theta}^{\text{d}}$ with

$$Z_{j,\theta}^{\text{od}} = \int_{\mathbb{R}^3} \mathcal{U}_\theta P_{p,j} \overline{G_x}(k) \bar{P}_{p,j} [H_p - \lambda_j + \omega(k) - i0]^{-1} \bar{P}_{p,j} G_x(k) P_{p,j} \mathcal{U}_\theta^{-1} dk, \quad (4.8)$$

$$Z_{j,\theta}^{\text{d}} = \int_{\mathbb{R}^3} \mathcal{U}_\theta P_{p,j} \overline{G_x}(k) P_{p,j} G_x(k) P_{p,j} \mathcal{U}_\theta^{-1} \frac{dk}{\omega(k)}. \quad (4.9)$$

Using the Leibniz rule and the fact that

$$\frac{d}{dz} \left[\bar{P}_\theta H_{0,\theta}^{\geq \sigma} - z \right]^{-1} = \left[\bar{P}_\theta H_{0,\theta}^{\geq \sigma} - z \right]^{-2}, \quad (4.10)$$

one can prove, by differentiating (4.6) with respect to z , that $z \mapsto b(z) := \lambda_j - z + a(z)$ is an analytic function on $D(\lambda_j, \sigma/2)$, and that $|db(z)/dz - 1| < 1$, provided that $g^2\sigma^{-1}$ is sufficiently small. This implies that b is a bijection on $D(\lambda_j, \sigma/2)$.

The isospectrality of the Feshbach map (see [3, 4]) tells us that

$$z \in \sigma(H_{g,\theta}^{\geq \sigma}) \iff 0 \in \mathcal{F}_{P_\theta}(H_{g,\theta}^{\geq \sigma} - z) \iff b(z) = 0.$$

On the other hand, it follows from the usual perturbation theory, applied to the isolated non-degenerate eigenvalue λ_j of $H_{0,\theta}^{\geq \sigma}$, that the spectrum of $H_{g,\theta}^{\geq \sigma}$ is not empty in $D(\lambda_j, \sigma/2)$, for g sufficiently small. Hence there exists a unique $\lambda_{j,g}^{\geq \sigma}$ in $D(\lambda_j, \sigma/2)$ such that $b(\lambda_{j,g}^{\geq \sigma}) = 0$, that is

$$\sigma(H_{g,\theta}^{\geq \sigma}) \cap D(\lambda_j, \frac{\sigma}{2}) = \{\lambda_{j,g}^{\geq \sigma}\}. \quad (4.11)$$

Note that for $g\sigma^{-1/2} \ll (d_j \sin(\text{Im}\theta))^2$ and any z in $D(\lambda_j, \sigma/2)$ the Neumann series

$$\left[\bar{P}_\theta H_{0,\theta}^{\geq \sigma} - z \right]^{-1} \sum_{n \geq 0} \left(-W_{g,\theta}^{\geq \sigma} \left[\bar{P}_\theta H_{0,\theta}^{\geq \sigma} - z \right]^{-1} \right)^n = \left[\bar{P}_\theta H_{g,\theta}^{\geq \sigma} \bar{P}_\theta - z \right]^{-1} \quad (4.12)$$

is convergent.

To prove (4.4), we use the following identity (see [3]):

$$\begin{aligned} \left[H_{g,\theta}^{\geq \sigma} - z \right]^{-1} &= \left[P_\theta - \left[\bar{P}_\theta \left(H_{g,\theta}^{\geq \sigma} - z \right) \bar{P}_\theta \right]^{-1} \bar{P}_\theta W_{g,\theta}^{\geq \sigma} P_\theta \right] \\ &\quad \left[\mathcal{F}_{P_\theta}(H_{g,\theta}^{\geq \sigma} - z) \right]^{-1} \left[P_\theta - P_\theta W_{g,\theta}^{\geq \sigma} \bar{P}_\theta \left[\bar{P}_\theta \left(H_{g,\theta}^{\geq \sigma} - z \right) \bar{P}_\theta \right]^{-1} \right] \\ &\quad + \left[\bar{P}_\theta \left(H_{g,\theta}^{\geq \sigma} - z \right) \bar{P}_\theta \right]^{-1} \bar{P}_\theta, \end{aligned} \quad (4.13)$$

which holds for z in $\rho(H_{g,\theta}^{\geq \sigma}) \cap D(\lambda_j, \sigma/2)$. The simple form of $\mathcal{F}_{P_\theta}(H_{g,\theta}^{\geq \sigma} - z)$, (4.12) and the fact that $|a(z) - a(\lambda_{j,g}^{\geq \sigma})| = O(g^{2+\varepsilon})$ by (4.7) lead to

$$\left\| \left[H_{g,\theta}^{\geq \sigma} - z \right]^{-1} \right\| \leq C_1 \left(\frac{1 + g^2\sigma^{-1}}{|z - \lambda_{j,g}^{\geq \sigma}| - C_2 g^{2+\varepsilon}} + \sigma^{-1} \right), \quad (4.14)$$

for some positive constants C_1, C_2 . Hence the proposition is proven for z in $D(\lambda_j, \sigma/3)$ such that $|z - \lambda_{j,g}^{\geq \sigma}| \gg g^{2+\varepsilon}$. \square

Recall that, for $g \geq 0$, $P_{g,\theta}^{\geq \sigma}$ denotes the projection onto the eigenspace associated with the eigenvalue $\lambda_{j,g}^{\geq \sigma}$ of $H_{g,\theta}^{\geq \sigma}$.

Proposition 4.2 *Let g, σ as in Proposition 4.1 and choose $\theta \in D(0, \theta_0)$ such that $\text{Im}\theta \neq 0$. Then, for g small enough,*

$$\left\| P_{g,\theta}^{\geq \sigma} - P_{0,\theta}^{\geq \sigma} \right\| \leq C_0 g \sigma^{-1/2}, \quad (4.15)$$

where C_0 is a positive constant.

Proof. Let \mathcal{C}_j denote a circle centered at λ_j , with radius $\sigma/3$, so that $\mathcal{C}_j \subset \rho(H_{g,\theta}^{\geq\sigma})$. Since we have assumed $g^2 \ll \sigma$, for g sufficiently small, \mathcal{C}_j contains both $\lambda_{j,g}^{\geq\sigma}$ and λ_j . Thus,

$$P_{g,\theta}^{\geq\sigma} - P_{0,\theta}^{\geq\sigma} = \oint_{\mathcal{C}_j} \left[R_{g,\theta}^{\geq\sigma}(z) - R_{0,\theta}^{\geq\sigma}(z) \right] dz. \quad (4.16)$$

We expand $R_{g,\theta}^{\geq\sigma}(z)$ into a Neumann series

$$R_{g,\theta}^{\geq\sigma}(z) = R_{0,\theta}^{\geq\sigma}(z) \sum_{n \geq 0} \left(-W_{g,\theta}^{\geq\sigma} R_{0,\theta}^{\geq\sigma}(z) \right)^n, \quad (4.17)$$

and we claim that, for all $n \geq 1$,

$$\left\| R_{0,\theta}^{\geq\sigma}(z) \left(-W_{g,\theta}^{\geq\sigma} R_{0,\theta}^{\geq\sigma}(z) \right)^n \right\| \leq \frac{C_1}{\sigma} \left(C_2 g \sigma^{-1/2} \right)^n. \quad (4.18)$$

Here C_1 and C_2 denote positive constants. The last estimate (4.18) could be proved by using the method of [5, Lemma 3.14]. Inserting this in (4.16) and using the fact that the radius of \mathcal{C}_j is equal to $\sigma/3$, we obtain

$$\left\| P_{g,\theta}^{\geq\sigma} - P_{0,\theta}^{\geq\sigma} \right\| = \left\| \oint_{\mathcal{C}_j} R_{0,\theta}^{\geq\sigma}(z) \sum_{n \geq 1} \left(-W_{g,\theta}^{\geq\sigma} R_{0,\theta}^{\geq\sigma}(z) \right)^n dz \right\| \leq C_0 g \sigma^{-1/2}, \quad (4.19)$$

provided that $g\sigma^{-1/2}$ is sufficiently small. Hence the proposition is proven. \square

We now estimate the difference between the eigenvalues $\lambda_{j,g}$ and $\lambda_{j,g}^{\geq\sigma}$ of $H_{g,\theta}$ and $H_{g,\theta}^\sigma$.

Proposition 4.3 *Suppose $0 < g^2 \ll \sigma < g^{\frac{3}{2+\mu}}$. Then*

$$\lambda_{j,g} - \lambda_{j,g}^{\geq\sigma} = O\left(g^{4 - \frac{3}{2+\mu}}\right). \quad (4.20)$$

Proof. For g and σ small enough, we choose $\theta \in D(0, \theta_0)$, $\text{Im}(\theta) \neq 0$, such that $0 < g\sigma^{-1/2} \ll (d_j \sin(\text{Im}\theta))^2 < 1$. For ρ such that $g\rho^{-1/2} \ll (d_j \sin(\text{Im}\theta))^2$, let $P_\theta := P_{\rho,j,\theta} \otimes \mathbf{1}_{H_f < \rho}$. Following [3, 5], $\lambda_{j,g}$ satisfies

$$|\lambda_{j,g} - \lambda_j - g^2 Z_{j,\theta}| \leq \sum_{i=1}^5 \|\text{Rem}_i\|, \quad (4.21)$$

where $Z_{j,\theta} := Z_{j,\theta}^{\text{od}} + Z_{j,\theta}^{\text{d}}$, with $Z_{j,\theta}^{\text{od}}$ and $Z_{j,\theta}^{\text{d}}$ given by (4.8) – (4.9), and

$$\text{Rem}_1 = P_\theta W_{g,\theta} P_\theta, \quad (4.22)$$

$$\text{Rem}_2 = P_\theta W_{g,\theta} \bar{P}_\theta \left[\bar{P}_\theta H_{0,\theta} - \lambda_{j,g} \right]^{-1} \bar{P}_\theta W_{g,\theta} P_\theta - g^2 Q_\theta \quad (4.23)$$

$$\text{Rem}_3 = g^2 \left[Q_\theta - Z_{j,\theta}^{\text{od}} - Z_{j,\theta}^{\text{d}} \right], \quad (4.24)$$

$$\text{Rem}_4 = P_\theta W_{g,\theta} \left(\bar{P}_\theta \left[\bar{P}_\theta H_{0,\theta} - \lambda_{j,g} \right]^{-1} \bar{P}_\theta W_{g,\theta} \right)^2 P_\theta, \quad (4.25)$$

$$\text{Rem}_5 = P_\theta W_{g,\theta} \sum_{n \geq 3} \left(\bar{P}_\theta \left[\bar{P}_\theta H_{0,\theta} - \lambda_{j,g} \right]^{-1} \bar{P}_\theta W_{g,\theta} \right)^n P_\theta. \quad (4.26)$$

Here we have set

$$Q_\theta = \int_{\mathbb{R}^3} P_\theta \overline{G_{x,\theta}(k)} \left[\frac{\overline{P_\theta(\omega(k))}}{H_{0,\theta} + e^{-\theta}\omega(k) - \lambda_{j,g}} \right] G_{x,\theta}(k) P_\theta dk. \quad (4.27)$$

where $\overline{P_\theta}(\omega(k)) := \mathbf{1} - P_\theta(\omega(k))$, and $P_\theta(\omega(k)) := P_{p,\theta} \otimes \mathbf{1}_{H_f + \omega(k) < \rho}$. Using the expression (2.3) of $G_{x,\theta}$ and estimates similar to [3, Lemmas IV.6-IV.12] or [5, Lemma 3.16], we claim that

$$\|\text{Rem}_1\| = O(g\rho^{1+\mu}), \quad \|\text{Rem}_2\| = O(g^2\rho^{1+\mu}), \quad \|\text{Rem}_3\| = O(g^2\rho). \quad (4.28)$$

The first bound in (4.28) easily follows from

$$\int_{\mathbb{R}^3} \|P_\theta \overline{G_{x,\theta}(k)} \otimes a^*(k)\| dk = \int_{\mathbb{R}^3} \|G_{x,\theta}(k) \otimes a(k) P_\theta\| dk \leq C\rho^{1+\mu}. \quad (4.29)$$

The second one follows from normal-ordering (4.23) and using again (4.29). Finally, the last bound in (4.28) follows from computing the difference in (4.24) and using the estimate

$$\left\| \frac{\overline{P_\theta}(\omega(k))}{H_{0,\theta} + e^{-\theta}\omega(k) - \lambda_{j,g}} \right\| \leq \frac{C_1}{(d_j \sin \text{Im}\theta)\omega(k)}, \quad (4.30)$$

for some positive constant C_1 . Now it is proved in [3, 5] that $\|\text{Rem}_4 + \text{Rem}_5\| = O(g^3\rho^{-1/2})$. Let us estimate these terms more precisely: we claim that

$$\|\text{Rem}_4\| = O(g^3\rho^\mu), \quad \|\text{Rem}_5\| = O(g^4\rho^{-1}). \quad (4.31)$$

To prove the first bound in (4.31), we decompose $W_{g,\theta}$ into $W_{g,\theta} = g(a^*(G_{x,\theta}) + a(G_{x,\theta}))$ and estimate each term separately by normal ordering. For instance, let us compute

$$\begin{aligned} & P_\theta a(G_{x,\theta}) \frac{\overline{P_\theta}}{H_{0,\theta} - \lambda_{j,g}} a^*(G_{x,\theta}) \frac{\overline{P_\theta}}{H_{0,\theta} - \lambda_{j,g}} a(G_{x,\theta}) P_\theta \\ &= P_\theta \int_{\mathbb{R}^9} G_{x,\theta}(k_1) \otimes a(k_1) \frac{\overline{P_\theta}}{H_{0,\theta} - \lambda_{j,g}} \overline{G_{x,\theta}(k_2)} \otimes a^*(k_2) \frac{\overline{P_\theta}}{H_{0,\theta} - \lambda_{j,g}} \\ & \quad G_{x,\theta}(k_3) \otimes a(k_3) P_\theta dk_1 dk_2 dk_3. \end{aligned} \quad (4.32)$$

It follows from a pull-through formula and the canonical commutation rules that the ‘‘worst’’ term we have to estimate from the rhs of (4.32) is

$$\begin{aligned} \text{T}(\rho, \theta) &:= P_\theta \int_{\mathbb{R}^6} G_{x,\theta}(k_1) \otimes \mathbf{1} \frac{\overline{P_\theta}(\omega(k_1))}{H_{0,\theta} + e^{-\theta}\omega(k_1) - \lambda_{j,g}} \overline{G_{x,\theta}(k_1)} \otimes \mathbf{1} \frac{\overline{P_\theta}}{H_{0,\theta} - \lambda_{j,g}} \\ & \quad G_{x,\theta}(k_3) \otimes a(k_3) P_\theta dk_1 dk_3. \end{aligned} \quad (4.33)$$

One can see that

$$\left\| \frac{\overline{P_\theta}}{H_{0,\theta} - \lambda_{j,g}} \right\| \leq \frac{C_1}{(d_j \sin \text{Im}\theta)\rho}, \quad (4.34)$$

for some positive constant C_1 . Inserting this together with (4.30) into (4.33), we get

$$\begin{aligned} \|\text{T}(\rho, \theta)\| &\leq \frac{C_1^2}{(d_j \sin \text{Im}\theta)^2} \rho^{-1} \int_{\mathbb{R}^3} \frac{|G_{x,\theta}(k_1)|^2}{\omega(k_1)} dk_1 \int_{\mathbb{R}^3} \|G_{x,\theta}(k_3) \otimes a(k_3) P_\theta\| dk_3 \\ &\leq \frac{C_2}{(d_j \sin \text{Im}\theta)^2} \rho^\mu, \end{aligned} \quad (4.35)$$

where C_2 is a positive constant. Since the other terms could be estimated in the same way, the first bound in (4.31) follows; the second bound in (4.31) can be obtained by using similar computations (see also [5, Lemma 3.16]).

For $\rho > \sigma$ the eigenvalue $\lambda_{j,g}^{\geq \sigma}$ of $H_{g,\theta}^{\geq \sigma}$ is given by the formulas (4.21)–(4.27), except that $W_{g,\theta}$ and $G_{x,\theta}(k)$ are replaced respectively by $W_{g,\theta}^{\geq \sigma}$ and $\kappa_\sigma(k)G_{x,\theta}(k)$. For the terms analogous to $Z_{j,\theta}^{\text{od}}$ and $Z_{j,\theta}^{\text{d}}$ we have by a straightforward computations that

$$\int_{|k| \leq \sigma} \mathcal{U}_\theta P_{p,j} \overline{G_x(k)} \overline{P_{p,j}} [H_p - \lambda_j + \omega(k) - i0]^{-1} \overline{P_{p,j}} G_x(k) P_{p,j} \mathcal{U}_\theta^{-1} dk = 0, \quad (4.36)$$

$$\int_{|k| \leq \sigma} \mathcal{U}_\theta P_{p,j} \overline{G_x(k)} P_{p,j} G_x(k) P_{p,j} \mathcal{U}_\theta^{-1} \frac{dk}{\omega(k)} = O(\sigma^{1+2\mu}), \quad (4.37)$$

where in (4.36) we used the fact that $\sigma < d_j$. Hence, with the obvious notation, $Z_{j,\theta} = Z_{j,\theta}^{\geq \sigma} + O(\sigma^{1+2\mu})$. Furthermore, Eqns (4.28)–(4.31) still hold for $\lambda_{j,g}^{\geq \sigma}$. Hence remembering the assumptions $\sigma < \rho$, $g^2 \ll \rho$ we obtain

$$\lambda_{j,g} - \lambda_{j,g}^{\geq \sigma} = O(g\rho^{1+\mu}) + O(g^2\rho) + O(g^4\rho^{-1}). \quad (4.38)$$

Optimizing with respect to ρ leads to the claim of the proposition. \square

Lemma 4.4 *Let θ in $D(0, \theta_0)$, $\text{Im}\theta > 0$ and let g, σ be such that $0 < g^2 \ll \sigma < g^{\frac{3}{2+\mu}} \ll 1$. Then for all $z \in \text{I}$ and $n \geq 1$, we have the estimate:*

$$\left\| \tilde{R}_{g,\theta}^\sigma(z) \left(\widetilde{W}_{g,\theta}^{\leq \sigma} \tilde{R}_{g,\theta}^\sigma(z) \right)^n \right\| \leq C_1 g^{-2} \left(C_2 (\sigma^{1/2+\mu} + g^{2-\frac{3}{2+\mu}}) \right)^n, \quad (4.39)$$

where C_1, C_2 are positive constants.

Proof. Recall that

$$\widetilde{W}_{g,\theta}^{\leq \sigma} = ga^*(G_{x,\theta}^{\leq \sigma}) + ga(G_{x,\theta}^{\leq \sigma}) + \left(\lambda_{j,g} - \lambda_{j,g}^{\geq \sigma} \right). \quad (4.40)$$

Let $\Gamma_\sigma = \Gamma(\mathbf{1}_{|k| \leq \sigma})$ be the second quantization of $\mathbf{1}_{|k| \leq \sigma}$. Note that $\mathcal{V}\Gamma_\sigma H_f \mathcal{V}^{-1} = I \otimes H_f^{\leq \sigma}$. Hence, from the spectral representation (3.17) and the decomposition (3.5), we can write

$$\tilde{R}_{g,\theta}^\sigma(z) = \widehat{R}_{g,\theta}^\sigma(z) + \mathcal{V}^{-1} (P_{g,\theta}^{\geq \sigma} \otimes I) \mathcal{V} \left[z - \lambda_{j,g}^{\geq \sigma} - e^{-\theta} \Gamma_\sigma H_f \right]^{-1}, \quad (4.41)$$

where $\widehat{R}_{g,\theta}^\sigma(z) := (I - \mathcal{V}^{-1} (P_{g,\theta}^{\geq \sigma} \otimes I) \mathcal{V}) \tilde{R}_{g,\theta}^\sigma(z)$. We have

$$\mathcal{V} \widehat{R}_{g,\theta}^\sigma(z) \mathcal{V}^{-1} = \int_{\sigma(H_f^{\leq \sigma})} \widehat{R}_{g,\theta}^{\geq \sigma}(z - e^{-\theta} x) \otimes dE_{H_f^{\leq \sigma}}(x). \quad (4.42)$$

It follows from Proposition 4.1 that $\|\widehat{R}_{g,\theta}^\sigma(z)\| = O(\sigma^{-1})$ for all z in I . Besides,

$$\left\| \left[z - \lambda_{j,g}^{\geq \sigma} - e^{-\theta} \Gamma_\sigma H_f \right]^{-1} \right\| \leq \left| \text{Im}(\lambda_{j,g}^{\geq \sigma}) \right|^{-1} = O(g^{-2}), \quad (4.43)$$

provided that Fermi's Golden Rule holds. Since Γ_σ commutes with $a(G_{x,\theta}^{\leq \sigma})$ and $a^*(G_{x,\theta}^{\leq \sigma})$, one can show by using a pull-through formula that

$$\left\| a(G_{x,\theta}^{\leq \sigma}) \left[z - \lambda_{j,g}^{\geq \sigma} - e^{-\theta} \Gamma_\sigma H_f \right]^{-1} \right\| = O(g^{-1} \sigma^{1/2+\mu}). \quad (4.44)$$

Similarly (4.42) leads to

$$\left\| a(G_{x,\theta}^{\leq\sigma}) \widehat{R}_{g,\theta}^\sigma(z) \right\| = O(\sigma^\mu). \quad (4.45)$$

The claim of the lemma then follows from (4.40) – (4.45), the assumption $g^2 \ll \sigma < g^{2+\mu}$, and Proposition 4.3. \square

5 Extension to non-relativistic QED

Now we extend the analysis above to the standard Hamiltonian of non-relativistic QED introduced in (1.1), Sect. 1. The results and proofs of Sections 3 - 4 go through without a change except for the proof of Lemma 3.4. In the non-relativistic QED case, $W_{g,\theta}$ is given by

$$W_{g,\theta} = \frac{g}{m} e^{-\theta} p \cdot A_\theta(x) + \frac{g^2}{2m} A_\theta(x) \cdot A_\theta(x) - \frac{g^2}{2m} \Lambda,$$

where we used the notation $p \cdot A_\theta(x) := i \sum_{j=1}^N \nabla_j \cdot A_\theta(x_j)$, and similarly for $A_\theta(x) \cdot A_\theta(x)$. The quantized vector potential $A_\theta(x_j)$ is given by (1.2), and $\Lambda := 2N \int \chi(k)^2 / |k| d^3k$. Here we set

$$W_{g,\theta}^{\leq\sigma} = \frac{g}{m} e^{-\theta} p \cdot A_\theta^{\leq\sigma}(x) + \frac{g^2}{m} A_\theta^{\leq\sigma}(x) \cdot A_\theta^{\geq\sigma}(x) + \frac{g^2}{2m} A_\theta^{\leq\sigma}(x) \cdot A_\theta^{\leq\sigma}(x) - \frac{g^2}{2m} \Lambda^{\leq\sigma},$$

where $\Lambda^{\leq\sigma} := 2N \int_{|k| \leq \sigma} \chi(k)^2 / |k| d^3k$. Hence the QED Hamiltonian satisfies the condition (2.9) with $\mu = 0$. We show now how to overcome this difficulty (a technique alternative to the one used here can be found in [2]).

In our sketch of the proof of Lemma 3.4 we begin with the most singular term B^1 of the expansion (3.34), Section 3. Thus we have to bound the term $\widetilde{R}_{g,\theta}^\sigma \widetilde{W}_{g,\theta}^{\leq\sigma} \widetilde{R}_{g,\theta}^\sigma$. The part of $\widetilde{W}_{g,\theta}^{\leq\sigma}$ involving the difference of the eigenvalues is estimated in the same way as before, and its norm is of order $O(\sigma g^{-3/2})$. The remaining part can be written as

$$\begin{aligned} W_{g,\theta}^{\leq\sigma} &= g[H_{g,\theta}^\sigma, x] \cdot A_\theta^{\leq\sigma}(x) + \frac{g^2}{2m} \left[A_\theta^{\leq\sigma}(x) \cdot A_\theta^{\leq\sigma}(x) - \Lambda^{\leq\sigma} \right] \\ &= g[H_{g,\theta}^\sigma, x] \cdot A_\theta^{\leq\sigma}(0) + \underbrace{g[H_{g,\theta}^\sigma, x] \cdot (A_\theta^{\leq\sigma}(x) - A_\theta^{\leq\sigma}(0))}_I + \underbrace{\frac{g^2}{2m} \left[A_\theta^{\leq\sigma}(x) \cdot A_\theta^{\leq\sigma}(x) - \Lambda^{\leq\sigma} \right]}_{II}, \end{aligned}$$

We can now rewrite the operator $\widetilde{R}_{g,\theta}^\sigma W_{g,\theta}^{\leq\sigma} \widetilde{R}_{g,\theta}^\sigma$ as

$$\begin{aligned} &gx \cdot A_\theta^{\leq\sigma}(0) \widetilde{R}_{g,\theta}^\sigma + g \widetilde{R}_{g,\theta}^\sigma \{ -x \cdot A_\theta^{\leq\sigma}(0) - e^{-\theta} \underbrace{gx \cdot [H_f, A_\theta^{\leq\sigma}(0)]}_{III} \} + \widetilde{R}_{g,\theta}^\sigma (I + II) \widetilde{R}_{g,\theta}^\sigma \\ &= -g[\widetilde{R}_{g,\theta}^\sigma, x \cdot A_\theta^{\leq\sigma}(0)] + \widetilde{R}_{g,\theta}^\sigma (I + II) \widetilde{R}_{g,\theta}^\sigma + \widetilde{R}_{g,\theta}^\sigma III \\ &= g \widetilde{R}_{g,\theta}^\sigma [H_{g,\theta}^\sigma, x \cdot A_\theta^{\leq\sigma}(0)] \widetilde{R}_{g,\theta}^\sigma + \widetilde{R}_{g,\theta}^\sigma (I + II) \widetilde{R}_{g,\theta}^\sigma + \widetilde{R}_{g,\theta}^\sigma III. \end{aligned}$$

The factor $\widetilde{R}_{g,\theta}^\sigma III \widetilde{R}_{g,\theta}^\sigma$ is bounded from above by $O(\sigma)$, see (2.9). In order to estimate the factors $g \widetilde{R}_{g,\theta}^\sigma [H_{g,\theta}^\sigma, x \cdot A_\theta^{\leq\sigma}(0)] \widetilde{R}_{g,\theta}^\sigma$, $\widetilde{R}_{g,\theta}^\sigma (I + II) \widetilde{R}_{g,\theta}^\sigma$ and $\widetilde{R}_{g,\theta}^\sigma III$, we pull $e^{-\delta \langle x \rangle}$ from Ψ_j until it hits $x \cdot A_\theta^{\leq\sigma}(0)$, I or III , which, using estimate (2.9), gives a term whose norm is of order $O(g^{-1} \sigma^{3/2})$. Therefore, $|B^1|$ is of order $O(\sigma g^{-3/2})$.

For the terms B^n with $n \geq 2$, one does a symmetric version of the estimates in Lemma 3.4. For example, for the term $B^2(t, \theta)$, we have the bound

$$\begin{aligned} |(\Psi_{j, \bar{\theta}}, \tilde{R}_{g, \theta}^\sigma W_{g, \theta}^{\leq \sigma} \tilde{R}_{g, \theta}^\sigma W_{g, \theta}^{\leq \sigma} \tilde{R}_{g, \theta}^\sigma \Psi_{j, \theta})| &\leq Cg^3 \underbrace{\|\tilde{R}_{g, \theta}^\sigma \langle p_\theta \rangle\|}_{O(g^{-2})} \underbrace{\|A_\theta^{\leq \sigma}(0) \tilde{R}_{g, \theta}^\sigma A_\theta^{\geq \sigma}(x) A_\theta^{\leq \sigma}(0) \tilde{R}_{g, \theta}^\sigma\|}_{O(\sigma^{\frac{3}{2}} g^{-2})} \\ &\leq C\sigma^{\frac{3}{2}} g^{-1}. \end{aligned}$$

Moreover, the most singular term in $B^2(t, \theta)$ involving the difference of the eigenvalues is

$$g|(\Psi_{j, \bar{\theta}}, \underbrace{\tilde{R}_{g, \theta}^\sigma (\lambda_{j, g} - \lambda_{j, g}^{\geq \sigma}) \mathcal{V}^{-1} P_{g, \theta}^{\geq \sigma}}_{O(g^{1/2})} \otimes I \mathcal{V} \underbrace{\tilde{R}_{g, \theta}^\sigma \langle p_\theta \rangle A_\theta^{\leq \sigma}(0) \tilde{R}_{g, \theta}^\sigma}_{O(\sigma^{1/2} g^{-3})} \Psi_{j, \theta})| \leq C\sigma^{1/2} g^{-3/2},$$

which, together with the factor of σ gained from integration, gives that $|B^2|$ is of order $O(\sigma^{3/2} g^{-3/2})$. Higher terms are evaluated similarly.

Instead of (3.39), Section 3, we have in the case of non-relativistic QED

$$(\Psi_j, e^{-itH_g} f(H_g) \Psi_j) = e^{-it\lambda_{j, g}} + O(g^2 \sigma^{-1}) + O(\sigma g^{-3/2}), \quad t \geq 0.$$

Optimizing and removing the f dependence as in the proof of Theorem 1.1 gives

$$(\Psi_j, e^{-itH_g} \Psi_j) = e^{-it\lambda_{j, g}} + O(g^{1/4}), \quad t \geq 0.$$

6 Resonances and poles of the resolvent

We discuss the characterization of dilatation resonances in terms of poles of the resolvent, which are ultimately connected to the poles that appear in scattering theory.

Consider the dilatations of electron positions and of photon momenta:

$$x_j \rightarrow e^\theta x_j \text{ and } k \rightarrow e^{-\theta} k,$$

where θ is a real parameter. Such dilatations are represented by unitary operators, U_θ , on the total Hilbert space $\mathcal{H} := \mathcal{H}_p \otimes \mathcal{F}_s$ of the system. There is a dense linear subspace $\mathcal{D} \subset \mathcal{H}$ of vectors with the property that, for every $\psi \in \mathcal{D}$, the family $\{U_\theta \psi\}_{\theta \in \mathbb{R}}$ of vectors has an analytic extension in θ to the entire complex plane, with $U_\theta \psi \in \mathcal{D}$, for any $\theta \in \mathbb{C}$. Vectors in \mathcal{D} are called dilatation-entire vectors.

Let H_g ($= H_g^{SM}$ or H_g^N) be the Hamiltonian of the system. We consider matrix elements of the resolvent

$$F_\psi(z) := (\psi, (H_g - z)^{-1} \psi),$$

for $z \in \mathbb{C}$, $\text{Im} z > 0$, and $\psi \in \mathcal{D}$. We will show below that, thanks to Conditions (A) and (B), of Sect. 1, on V and χ respectively, for all vectors $\psi \in \mathcal{D}$, $F_\psi(z)$ has an analytic continuation in z across the spectrum of H_g to the “second Riemann sheet”. We are interested in the behaviour of this analytic continuation.

For $z_* \in \mathbb{C}$ and $0 \leq \varphi_1 < \varphi_2 < 2\pi$ we define domains

$$W_{z_*}^{\varphi_1, \varphi_2} := \{z \in \mathbb{C} \mid |z - z_*| < \frac{1}{2} |\text{Im} z_*|, \varphi_1 \leq \arg(z - z_*) \leq \varphi_2\}.$$

Definition 6.1 We say that z_* , with $\text{Im}z_* < 0$, is a (quantum) resonance energy of H_g iff there is a dense set, $\mathcal{D}' \subset \mathcal{D}$, s.t. $\forall \psi \in \mathcal{D}'$, the function $F_\psi(z)$ has an analytic continuation in z from the upper half-plane into the domain $W_{z_*}^{\varphi_1, \varphi_2}$, for some $\varphi_1 < \pi/2$ and $\varphi_2 > \pi$, such that

$$F_\psi(w) = \frac{p(\psi)}{w - z_*} + r(w; \psi), \quad (\text{i})$$

with

$$|r(w; \psi)| \leq C(\psi)|w - z_*|^{-\alpha}, \quad (\text{ii})$$

for some $\alpha < 1$. Here $p(\psi)$ and $r(w; \psi)$ are quadratic forms on the domain $\mathcal{D}' \times \mathcal{D}'$.

One can show that within a certain range, the location of the poles is independent of the choice of set \mathcal{D}' . In the theorem below on existence of resonances the set \mathcal{D}' is chosen explicitly as

$$\mathcal{D}' := \{\psi \in \mathcal{D} \mid \|d\Gamma(\omega^{-1/2})(1 - P_\Omega)\psi\| < \infty\}$$

where P_Ω is the projection on the vacuum Ω in \mathcal{F}_s . Since $U_\theta d\Gamma(\omega^{-1/2}) = e^{\theta/2} d\Gamma(\omega^{-1/2})U_\theta$, the set \mathcal{D}' is dense in \mathcal{D} . We have the following theorem.

Theorem 6.2 Consider the Hamiltonian H_g . Let conditions (A) and (B) and (2.9) with $\mu > 1/2$ be satisfied, and let λ_j be an eigenvalue of H_p for which condition (C) in Section 1 holds. Then there is g_* s.t. for $g \leq g_*$ the Hamiltonian H_g has a resonance, $\lambda_{j,g}$, in the sense of Definition 6.1, above (see (i) and (ii)), with $\lambda_{j,g} = \lambda_j + O(g)$ and $\text{Im}\lambda_{j,g} \leq -\text{const. } g^2$.

Proof. The RG analysis [3, 4, 6, 14] shows that given $\delta > 0$, there are $g_* > 0$ and $\varphi_* \in (0, \varphi_0)$ s.t. for $g \leq g_*$ and $\text{Im}\theta \in (\varphi_*, \varphi_0)$, the spectrum of the operator $H_{g,\theta}$ in the half space $\{\text{Re}z \leq \Sigma + \delta\}$ lies in the union of wedges

$$S_j := \lambda_{j,g} + \{z \in \mathbb{C} \mid |\arg(z) + \text{Im}\theta| \leq \epsilon\},$$

where $\lambda_{j,g} = \lambda_j + O(g)$, $\text{Im}\lambda_{j,g} \leq 0$, $\text{Im}\lambda_{j,g} = O(g^2)$ and ϵ is sufficiently small. Moreover, the apices, $\lambda_{j,g}$, of these wedges are the eigenvalues of $H_{g,\theta}$. If in addition, condition (C) holds for λ_j then $\text{Im}\lambda_{j,g} \leq -\text{const. } g^2$.

We take $z \in W_{\lambda_{j,g}}^{\varphi_1, \varphi_2}$ with $\varphi_1 = \pi/2 - \varphi_0$ and $\varphi_2 > 3\pi/2 - \varphi_*$. We want to estimate $(\psi, (H_{g,\theta} - z)^{-1}\psi)$. Using an infrared cut-off as in section 2, we decompose

$$H_{g,\theta} = \tilde{H}_{g,\theta}^\sigma + \tilde{W}_{g,\theta}^{\leq \sigma}, \quad (\text{6.1})$$

see (2.16). The infrared cut-off Hamiltonian $\tilde{H}_{g,\theta}^\sigma$ has an eigenvalue at $\lambda_{j,g}$. We use the second resolvent equation

$$(H_{g,\theta} - z)^{-1} = (\tilde{H}_{g,\theta}^\sigma - z)^{-1} + (\tilde{H}_{g,\theta}^\sigma - z)^{-1} \tilde{W}_{g,\theta}^{\leq \sigma} (H_{g,\theta} - z)^{-1}. \quad (\text{6.2})$$

Let $\tilde{R}_g^\sigma(z) := (\tilde{H}_{g,\theta}^\sigma - z)^{-1}$ and let $P_\Omega^{\leq \sigma}$ is the projection onto the vacuum state of $\mathcal{F}_s^{\leq \sigma}$ and $\bar{P} = 1 - P$. Then

$$\tilde{R}_g^\sigma(z) = \frac{P_{g,\theta}^{\geq \sigma} \otimes P_\Omega^{\leq \sigma}}{\lambda_{j,g} - z} + \frac{P_{g,\theta}^{\geq \sigma} \otimes \bar{P}_\Omega^{\leq \sigma}}{\lambda_{j,g} + e^{-\theta} H_f^{\leq \sigma} - z} + \hat{R}^\sigma(z), \quad (\text{6.3})$$

where, as above,

$$\hat{R}^\sigma(z) := (\bar{P}_{g,\theta}^{\geq \sigma} \otimes I^{\leq \sigma}) \tilde{R}^\sigma(z). \quad (\text{6.4})$$

By our condition on z we can pick θ so that

$$\operatorname{Re}(e^\theta(\lambda_{j,g} - z)) \geq 0,$$

i.e. $|\operatorname{Im}\theta + \arg(\lambda_{j,g} - z)| \leq \pi/2$. Then

$$\left| \left(\psi, \frac{P_{g,\theta}^{\geq\sigma} \otimes \overline{P}_\Omega^{\leq\sigma}}{\lambda_{j,g} + e^{-\theta} H_f^{\leq\sigma} - z} \psi \right) \right| \leq \| (H_f^{\leq\sigma})^{-1/2} \overline{P}_\Omega^{\leq\sigma} \psi \|^2. \quad (6.5)$$

(More generally, the l.h.s. is bounded by $|\lambda_{j,g} - z|^{-\alpha} \| (H_f^{\leq\sigma})^{-(1-\alpha)/2} \overline{P}_\Omega^{\leq\sigma} \psi \|^2$ for $0 \leq \alpha \leq 1$.) Furthermore, an elementary analysis of the n -photon sectors shows that

$$\| (H_f^{\leq\sigma})^{-1/2} \overline{P}_\Omega^{\leq\sigma} \psi \| \leq \| d\Gamma(\omega^{-1/2}) \overline{P}_\Omega \psi \|. \quad (6.6)$$

Hence, by the definition of \mathcal{D}' we have $\forall \psi \in \mathcal{D}'$ that

$$\left| \left(\psi, \frac{P_{g,\theta}^{\geq\sigma} \otimes \overline{P}_\Omega^{\leq\sigma}}{\lambda_{j,g} + e^{-\theta} H_f^{\leq\sigma} - z} \psi \right) \right| \leq C. \quad (6.7)$$

Next, using Eqn (6.4) and applying to $H_{g,\theta}^{\geq\sigma}$ a renormalization group analysis as in [3, 5, 6, 14], one can show that for $|z - \lambda_{j,g}| \leq \sigma/2$

$$\| (1 + H_f) \widehat{R}^\sigma(z) \| \leq C/\sigma, \quad (6.8)$$

for some constant C . Eqns (6.3), (6.7) and (6.8) imply that for $\psi \in \mathcal{D}'$

$$\left\| \left(\psi, \left(\widetilde{R}_g^\sigma(z) - \frac{P_{g,\theta}^{\geq\sigma} \otimes P_\Omega^{\leq\sigma}}{\lambda_{j,g} - z} \right) \psi \right) \right\| \leq C/\sigma, \quad (6.9)$$

Finally we estimate the last term on the r.h.s. Eqn (6.2). Recall that

$$\widetilde{W}_{g,\theta}^{\leq\sigma} = W_{g,\theta}^{\leq\sigma} - \left(\lambda_{j,g} - \lambda_{j,g}^{\geq\sigma} \right) \mathcal{V}^{-1} (P_{g,\theta}^{\geq\sigma} \otimes I) \mathcal{V}, \quad (6.10)$$

where

$$W_{g,\theta}^{\leq\sigma} := W_{g,\theta} - W_{g,\theta}^{\geq\sigma} = g\phi((1 - \kappa_\sigma) G_{x,\theta}). \quad (6.11)$$

Below we will choose $\sigma \rightarrow 0$ as $|\lambda_{j,g} - z| \rightarrow 0$. Hence we have to estimate $\lambda_{j,g} - \lambda_{j,g}^{\geq\sigma}$ for any $\sigma > 0$. We claim that

$$|\lambda_{j,g} - \lambda_{j,g}^{\geq\sigma}| = O\left((g\sigma^{1/2+\mu})^2\right). \quad (6.12)$$

This estimate is proven in the proposition at the end of this section.

Iterating the last term on the r.h.s. Eqn (6.2) we see that the worst term is $\widetilde{R}_g^\sigma \widetilde{W}_{g,\theta}^{\leq\sigma} \widetilde{R}_g^\sigma$. We use the decomposition (6.3). Since the operator $W_{g,\theta}^{\leq\sigma}$ is in a normal form we see that the term coming from sandwiching it by the first term on the r.h.s. of (6.3) vanishes. Thus it remains to consider the terms

$$\begin{aligned} & \widetilde{R}_g^\sigma \left(\lambda_{j,g} - \lambda_{j,g}^{\geq\sigma} \right) \left(P_{g,\theta}^{\geq\sigma} \otimes I \right) \widetilde{R}_g^\sigma, \quad (6.13) \\ & \left[\frac{P_{g,\theta}^{\geq\sigma} \otimes P_\Omega^{\leq\sigma}}{\lambda_{j,g} - z} + \frac{P_{g,\theta}^{\geq\sigma} \otimes \overline{P}_\Omega^{\leq\sigma}}{\lambda_{j,g} + e^{-\theta} H_f^{\leq\sigma} - z} + \widehat{R}^\sigma(z) \right] \end{aligned}$$

$$\times W_{g,\theta}^{\leq\sigma} \left[\frac{P_{g,\theta}^{\geq\sigma} \otimes \overline{P}_\Omega^{\leq\sigma}}{\lambda_{j,g} + e^{-\theta} H_f^{\leq\sigma} - z} + \widehat{R}^\sigma(z) \right] \quad (6.14)$$

and the term obtained by switching the right and left factors in the term above.

To estimate we note that, by the decomposition (6.3) and the definition of $\widehat{R}^\sigma(z)$, Eqn (6.14) can be written as

$$\begin{aligned} & \left(\lambda_{j,g} - \lambda_{j,g}^{\geq\sigma} \right) \frac{P_{g,\theta}^{\geq\sigma} \otimes P_\Omega^{\leq\sigma}}{(\lambda_{j,g} - z)^2} \\ & + \left(\lambda_{j,g} - \lambda_{j,g}^{\geq\sigma} \right) \frac{P_{g,\theta}^{\geq\sigma} \otimes \overline{P}_\Omega^{\leq\sigma}}{(\lambda_{j,g} + e^{-\theta} H_f^{\leq\sigma} - z)^2}. \end{aligned} \quad (6.15)$$

Using (6.12) we obtain the following estimate for (6.13);

$$(6.13) = O\left((g\sigma^{1/2+\mu} |\lambda_{j,g} - z|^{-1})^2 \right). \quad (6.16)$$

To estimate (6.14) we observe first that due to we have that for $n = 0, 1$

$$\|(H_f^{\leq\sigma})^n (\lambda_{j,g} + e^{-\theta} H_f^{\leq\sigma} - z)^{-1}\| \leq C |\lambda_{j,g} - z|^{n-1}, \quad (6.17)$$

Assume $\sigma \geq |z - \lambda_{j,g}|$. Using estimates (2.9), (6.8) and (6.17), the fact that $P_\Omega^{\leq\sigma} a^*((1 - \kappa_\sigma)G_{x,\theta}) = 0$ and standard estimates on the creation and annihilation operators and remembering the condition $\text{Re}(e^\theta(\lambda_{j,g} - z)) \geq 0$, we obtain

$$\|\widetilde{R}_g^\sigma W_{g,\theta}^{\leq\sigma} \widetilde{R}_g^\sigma\| \leq C \frac{1}{|z - \lambda_{j,g}|} g\sigma^{\frac{1}{2}+\mu} \left(\frac{\sigma^{1/2}}{|z - \lambda_{j,g}|^{1/2}} + \frac{1}{\sigma} \right). \quad (6.18)$$

This together with (6.16) gives

$$\|\widetilde{R}_g^\sigma \widetilde{W}_{g,\theta}^{\leq\sigma} \widetilde{R}_g^\sigma\| \leq C \frac{g\sigma^{\frac{1}{2}+\mu}}{|z - \lambda_{j,g}|} \left(\frac{1}{\sigma} + \frac{\sigma^{1/2}}{|z - \lambda_{j,g}|^{1/2}} + \frac{g\sigma^{\frac{1}{2}+\mu}}{|z - \lambda_{j,g}|} \right). \quad (6.19)$$

Since, as we mentioned, the higher order iterants of (6.2) are estimated similarly and lead to improved estimates, we conclude, assuming $|z - \lambda_{j,g}|^{1/3} \geq \sigma \geq |z - \lambda_{j,g}|$, that

$$\|\widetilde{R}_g^\sigma \widetilde{W}_{g,\theta}^{\leq\sigma} R_{g,\theta}\| \leq C \frac{g\sigma^{-\frac{1}{2}+\mu}}{|z - \lambda_{j,g}|}, \quad (6.20)$$

where $R_{g,\theta}(z) := (H_{g,\theta} - z)^{-1}$.

It follows from (6.2), (6.9) and (6.20) that, for g small enough,

$$\|(\psi, ((H_{g,\theta} - z)^{-1} - \frac{1}{\lambda_{j,g} - z} P_{g,\theta}^{\geq\sigma} \otimes P_\Omega^{\leq\sigma}) \psi)\| \leq C \left(\frac{1}{\sigma} + \frac{g\sigma^\alpha}{r\sigma} \right), \quad (6.21)$$

where $r := |z - \lambda_{j,g}|$ and $\alpha := 1/2 + \mu$, for some constant C , provided $|z - \lambda_{j,g}|^{1/3} \geq \sigma \geq |z - \lambda_{j,g}|$. Pick $\sigma = \epsilon(\frac{r}{g})^{1/\alpha}$, where ϵ is independent of g and r . By our assumption $\alpha := 1/2 + \mu > 1$ and therefore $\sigma > r$. Then for this σ

$$\|(\psi, ((H_{g,\theta} - z)^{-1} - \frac{1}{\lambda_{j,g} - z} P_{g,\theta}^{\geq\sigma} \otimes P_\Omega^{\leq\sigma}) \psi)\| \leq C\epsilon^{-1} \left(\frac{g}{r} \right)^{1/\alpha}.$$

The last estimate together with the relation

$$(\psi, (H_g - z)^{-1} \psi) = (\psi_{\bar{\theta}}, (H_{g,\theta} - z)^{-1} \psi_\theta), \quad (6.22)$$

implies (i) and (ii) in Definition 6.1 with $\alpha = (1/2 + \mu)^{-1}$. \square

Proposition 6.3 *Under the conditions of Theorem 6.2, the estimate (6.12) holds for any $\sigma > 0$.*

Proof. To prove (6.12) we use the RG approach. Here we point out particularities of the present problem and outline the general strategy, technical details can be found in [3, 4, 6, 14]. Since we do not go into details, we use the Feshbach-Schur map, rather than the smooth Feshbach-Schur map to underpin our construction. The former ([3, 4]) is simpler to formulate but the latter ([6, 14]) is easier to handle technically. Our strategy follows ([14]).

First we apply the Feshbach-Schur map $\mathcal{F}_{P_{\rho_0}}$ with the projection $P_{\rho} := P_{g,\theta}^{\geq\sigma} \otimes \chi_{\rho}^{\leq\sigma}$ where $\chi_{\rho}^{\leq\sigma} := \chi_{H_f^{\leq\sigma} \leq \rho}$. For $z \in D(\lambda_{j,g}^{\geq\sigma}, \sigma/2)$ and $\rho_0 = \sigma$, the operator $H_{g,\theta} - z$ is in the domain of $\mathcal{F}_{P_{\rho_0}}$. Indeed, an easy estimate shows that the operator $\bar{P}_{\rho_0} H_{g,\theta}^{\sigma} \bar{P}_{\rho_0} - z$ is invertible on $\text{Ran} \bar{P}_{\rho_0}$ and $\|[H_f + 1] \bar{P}_{\rho_0} [\bar{P}_{\rho_0} H_{g,\theta}^{\sigma} \bar{P}_{\rho_0} - z]^{-1} \bar{P}_{\rho_0}\| \leq C/\sigma$. Since $\|W_{g,\theta}^{\leq\sigma} [H_f + 1]^{-1}\| \leq Cg\sigma^{1/2+\mu}$, we see by the Neumann series argument that the operator $\bar{P}_{\rho_0} H_{g,\theta} \bar{P}_{\rho_0} - z$ is invertible on $\text{Ran} \bar{P}_{\rho_0}$ and $\|\bar{P}_{\rho_0} [\bar{P}_{\rho_0} H_{g,\theta} \bar{P}_{\rho_0} - z]^{-1} \bar{P}_{\rho_0}\| \leq C/\sigma$. Hence the operator $H_{g,\theta} - z$ is in the domain of $\mathcal{F}_{P_{\rho_0}}$, as claimed. Now we have

$$\mathcal{F}_{P_{\rho_0}}(H_{g,\theta} - z) = P_{g,\theta}^{\geq\sigma} \otimes H_z,$$

where the operator H_z acts on $\text{Ran} \chi_{\rho_0}^{\leq\sigma} \subset \mathcal{F}_s^{\leq\sigma}$ and is given by

$$H_z := \chi_{\rho_0}^{\leq\sigma} (\psi_{g,\theta}^{\geq\sigma}, (\lambda_{j,g}^{\geq\sigma} - z + H_f^{\leq\sigma} + W_{g,\theta}^{\leq\sigma} + U) \psi_{g,\theta}^{\geq\sigma}) \chi_{\rho_0}^{\leq\sigma}, \quad (6.23)$$

where $U := -W_{g,\theta}^{\leq\sigma} \bar{P}_{\rho_0} [\bar{P}_{\rho_0} H_{g,\theta} \bar{P}_{\rho_0} - z]^{-1} \bar{P}_{\rho_0} W_{g,\theta}^{\leq\sigma}$.

By the isospectrality of the Feshbach-Schur map (see [3, 4, 5, 6, 14]), we have that $z \in D(\lambda_{j,g}^{\geq\sigma}, \sigma/2)$ is an eigenvalue of $H_{g,\theta}$ iff 0 is an eigenvalue of H_z . To investigate the spectral properties H_z we apply to it the renormalization group.

As the first step we bring the operator H_z to the generalized normal form. To this end we expand the resolvent on the r.h.s. in the Neumann series in $W_{g,\theta}^{\leq\sigma}$ and normal order the creation and annihilation operators not entering the expression for $H_f^{\leq\sigma}$. This brings the operator H_z to the form (see [3, 4, 6, 14])

$$H_z := \chi_{\rho_0}^{\leq\sigma} (E_z + T_z + W_z) \chi_{\rho_0}^{\leq\sigma}, \quad (6.24)$$

where E_z is a number (more precisely, a complex function of z and other parameters), T_z is a differentiable function of $H_f^{\leq\sigma}$ and W_z is an operator in the generalized normal form which is a sum of terms with at least one creation or annihilation operator. A standard computation gives $E_z := \lambda_{j,g}^{\geq\sigma} - z + \Delta E_z$, with

$$\Delta E_z := - \int (\psi_{g,\theta}^{\geq\sigma}, G_{x,\theta}^{\leq\sigma}(k) \bar{P}_{g,\theta}^{\geq\sigma} [\bar{P}_{g,\theta}^{\geq\sigma} H_{g,\theta}^{\geq\sigma} \bar{P}_{g,\theta}^{\geq\sigma} + e^{-\theta} \omega - z]^{-1} \bar{P}_{g,\theta}^{\geq\sigma} G_{x,\theta}^{\leq\sigma}(k) \psi_{g,\theta}^{\geq\sigma}) dk + h.o.t.,$$

$$T_z := H_f^{\leq\sigma} - \int (\psi_{g,\theta}^{\geq\sigma}, G_{x,\theta}^{\leq\sigma}(k) \bar{P}_{\rho_0} [\bar{P}_{\rho_0} (H_{g,\theta}^{\geq\sigma} + e^{-\theta} (H_f^{\leq\sigma} + \omega)) \bar{P}_{\rho_0} - z]^{-1} \bar{P}_{\rho_0} G_{x,\theta}^{\leq\sigma}(k) \psi_{g,\theta}^{\geq\sigma}) dk + h.o.t.,$$

$$W_z := (\psi_{g,\theta}^{\geq\sigma}, (W_{g,\theta}^{\leq\sigma} - \int \int G_{x,\theta}^{\leq\sigma}(k) a^*(k) \bar{P}_{\rho_0} [\bar{P}_{\rho_0} (H_{g,\theta}^{\geq\sigma} + e^{-\theta} (H_f^{\leq\sigma} + \omega + \omega')) \bar{P}_{\rho_0} - z]^{-1} \bar{P}_{\rho_0} a(k') G_{x,\theta}^{\leq\sigma}(k') dk dk') \psi_{g,\theta}^{\geq\sigma}) + h.o.t..$$

Clearly,

$$\Delta E_z = O\left((g\sigma^{1/2+\mu})^2\right) \text{ and } \chi_{\rho_0}^{\leq\sigma} W_z \chi_{\rho_0}^{\leq\sigma} = O(g\sigma^{1+\mu}). \quad (6.25)$$

We define the *scaling transformation* $S_\rho : \mathcal{B}[\mathcal{F}_s^{\leq\sigma}] \rightarrow \mathcal{B}[\mathcal{F}_s^{\leq\sigma/\rho}]$, by

$$S_\rho(\mathbf{1}) := S_\rho(a^\#(k)) := \rho^{-3/2} a^\#(\rho^{-1}k), \quad (6.26)$$

where $a^\#(k)$ is either $a(k)$ or $a^*(k)$ and $k \in \mathbb{R}^3$, and the dilation transform, by $A_\rho(A) := \rho^{-1}A$. Now we rescale the operator H_z as $H_z^{(0)} := A_\sigma(S_\sigma(H_z))$. The new operator acts on $\text{Ran}\chi_1^{\leq 1} \subset \mathcal{F}_s^{\leq 1}$. The last estimate in (6.25) and an estimate on the derivative of T_z as a function of $H_f^{\leq\sigma}$, which we do not display here, show that the operator $H_z^{(0)}$ is in the domain of the Feshbach-Schur map $\mathcal{F}_{\chi_\rho^{\leq\sigma}}$ and therefore in the domain the renormalization map \mathcal{R}_ρ , provided $1/2 \geq \rho \gg g\sigma^\mu$ and $\rho \gg |E_z|/\sigma$ (the latter inequality is also considered as a restriction on z).

If we neglect the term W_z in $H_z^{(0)}$ (see (6.24)) then the remaining operator has the eigenvector Ω with the eigenvalue 0, provided z solves the equation $E_z^{(0)} := (\Omega, H_z^{(0)}\Omega) = E_z/\sigma = 0$. One can show ([14]) that this equation has a unique solution $\lambda_{j,g}^{(1)} = \lambda_{j,g}^{\geq\sigma} + O((g\sigma^{1/2+\mu})^2)$. By the isospectrality mentioned above, this is our first approximation to $\lambda_{j,g}$.

Now we introduce the decimation map $F_\rho := \mathcal{F}_{\chi_\rho^{\leq\sigma}}$. On the domain of the decimation map F_ρ we define the renormalization map \mathcal{R}_ρ as ³

$$\mathcal{R}_\rho := A_\rho \circ S_\rho \circ F_\rho. \quad (6.27)$$

By the above, the operator $H_z^{(0)}$ is in the domain of the decimation map \mathcal{F}_ρ and therefore in the domain the renormalization map \mathcal{R}_ρ , provided $1/2 \geq \rho \gg g\sigma^\mu$ and $\rho \gg |E_z|/\sigma$. Iterating this map as in [14] we obtain a sequence of the operators $H_z^{(n)}$, $n = 0, 1, 2, \dots$, (Hamiltonians on scales $0, 1, \dots$) acting on the space $\text{Ran}\chi_1^{\leq 1} \subset \mathcal{F}_s^{\leq 1}$. Again one argues that 0 is an approximate eigenvalue of the operators $H_z^{(n)}$ provided z satisfies the equations $E_z^{(n)} := (\Omega, H_z^{(n)}\Omega) = 0$. Again the latter equations have unique solutions $\lambda_{j,g}^{(n)} = \lambda_{j,g}^{\geq\sigma} + O((g\sigma^{1/2+\mu})^2)$ and, again, by the isospectrality of \mathcal{R}_ρ , this produces our approximations, $\lambda_{j,g}^{(n)}$, to $\lambda_{j,g}$. Finally one shows that $\lambda_{j,g}^{(n)} \rightarrow \lambda_{j,g}$ as $n \rightarrow \infty$ which allows us to conclude that the operator $H_z^{(0)}$ has a simple eigenvalue 0 provided $z = \lambda_{j,g}$. Hence, by the isospectrality mentioned above, the operator $H_{g,\theta}$ has a unique eigenvalue $\lambda_{j,g}$ in the disc $D(\lambda_{j,g}^{\geq\sigma}, \sigma/2)$ and this eigenvalue satisfies (6.12). \square
